Nicolas Flammarion

Convolutional Networks

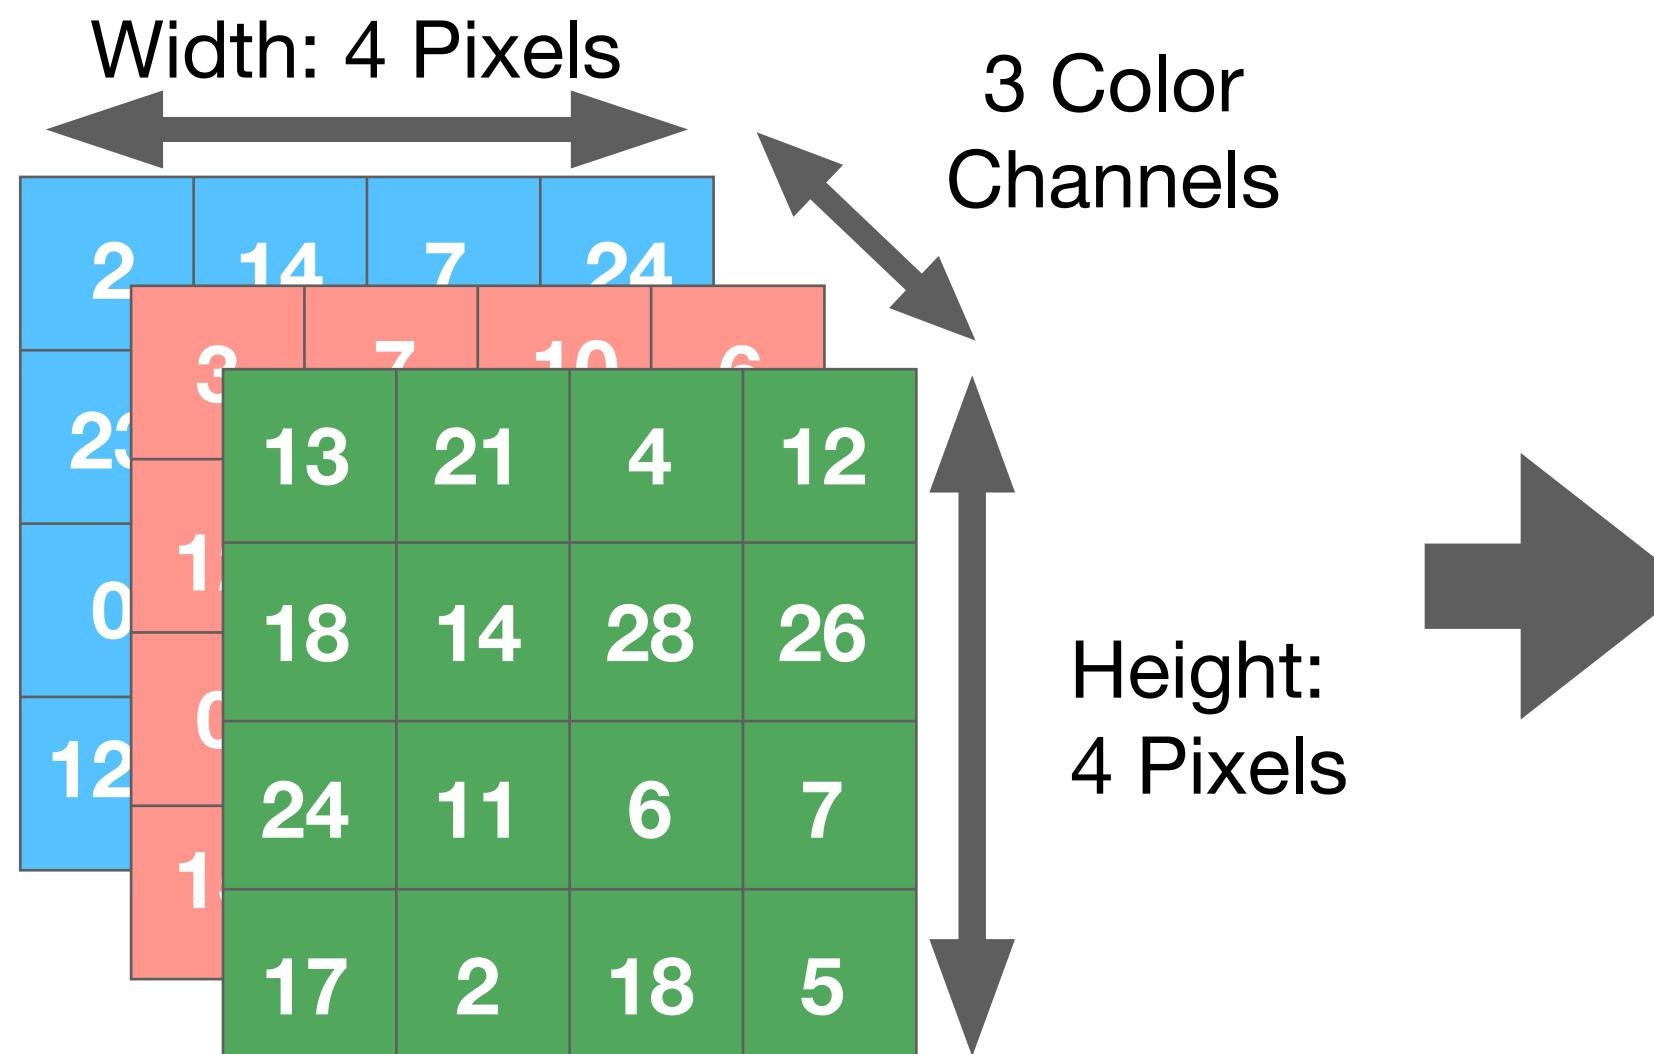

Convolutional NNs: General Structure

- Convolutional networks consist of **sparsely connected convolutional layers** in place of fully-connected linear layers
- **Pooling layers** perform spatial downsampling (typically reducing the dimensions from $H \times W$ to $H/2 \times W/2$)
- A fully-connected network at the end performs classification based on the extracted features

Fully connected NNs have many parameters and do not capture spatial dependencies

- Fully connected NNs have $O(K^2L)$ parameters: training requires a lot of data

ImageNet Dimension:
 $256 \times 256 \times 3 \sim 2 \cdot 10^5$

- Fully connected neural networks interpret an image as a flattened vector, disregarding the original spatial dependencies

Convolution

$$x_{n,m}^{(1)} = \sum_{k,l} f_{k,l} \cdot x_{n-k,m-l}^{(0)}$$

- We consider local filters: $f_{k,l} \neq 0$ for small values of $|k|$ and $|l|$
 - ➡ $x_{n,m}^{(1)}$ only depends on the value of $x^{(0)}$ close to (n, m)
 - ➡ f represents the learnable weights
- We use the same filter at every position - **weight sharing**
- **Shift equivariance** - a shifted input results in a shifted output

1	0	1	1	0
1	1	0	1	1
0	0	1	1	0
0	1	1	0	0
1	1	1	0	1

Image

Convolved Feature

➡ Few parameters and features generalize between locations

Handling of borders

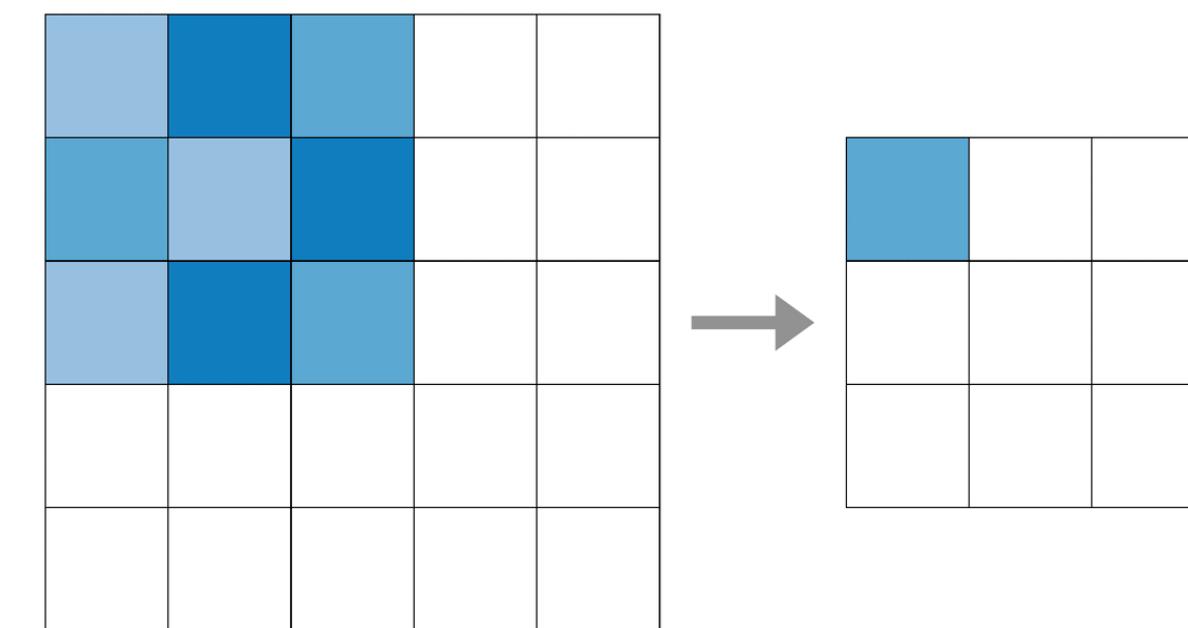

Zero padding:

Add zeros to each side of the input's boundaries

→ The convolved feature has the same dimension as the input

Valid padding:

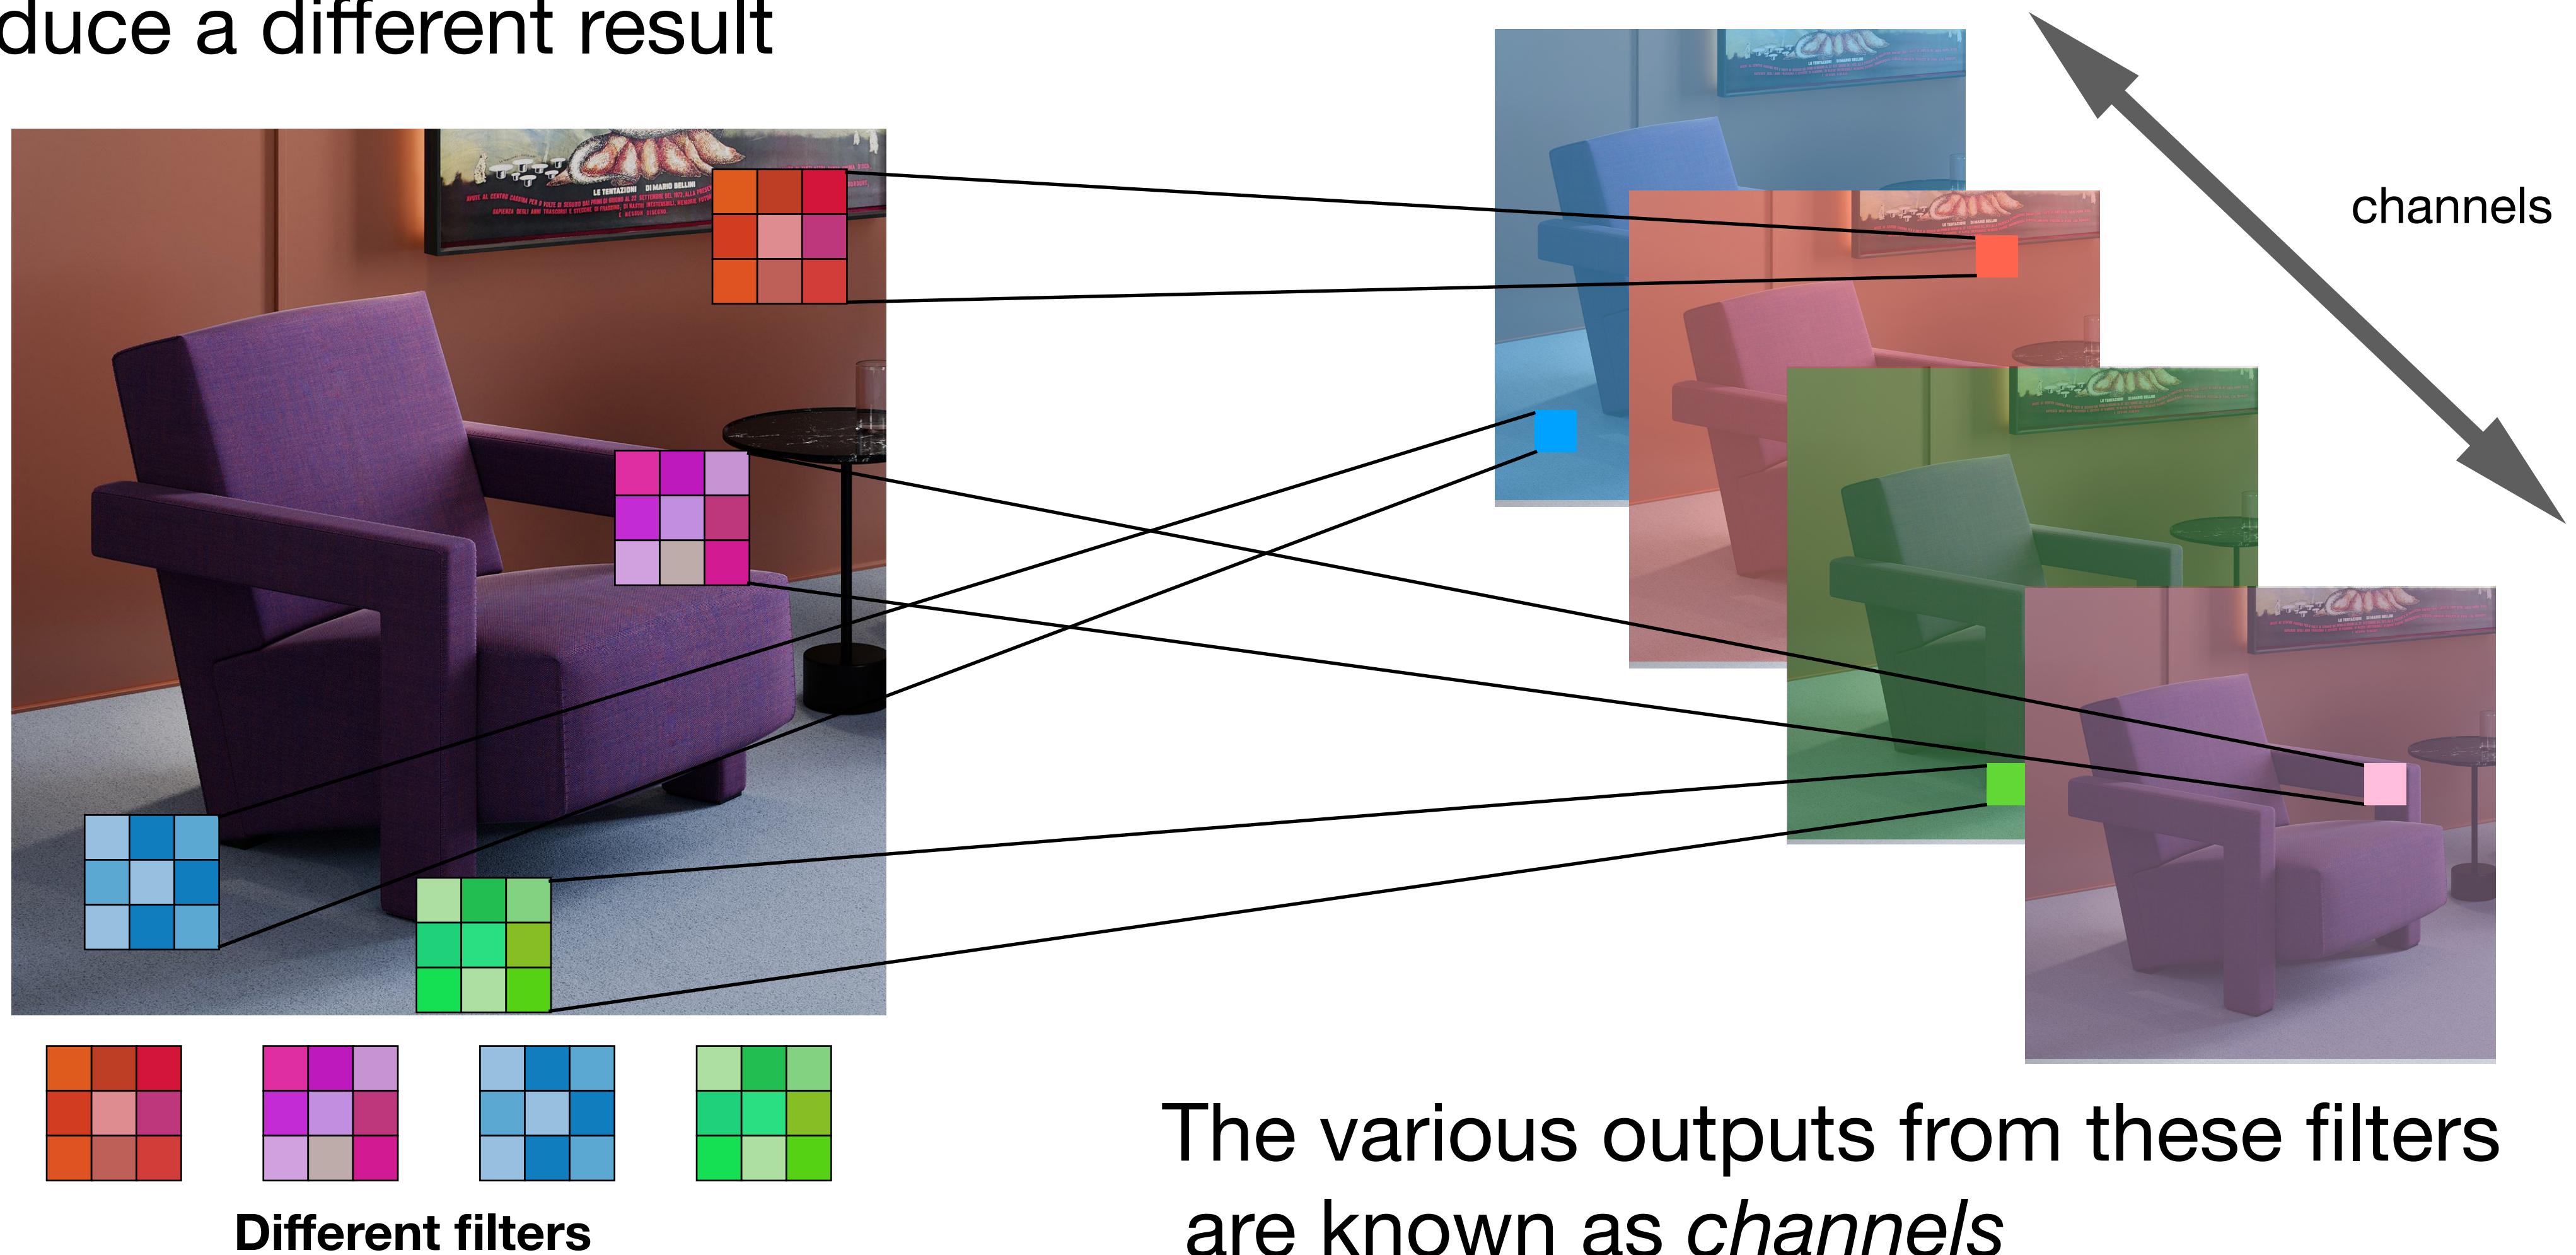

Perform the convolution only where the entire filter fits inside the original data

→ The convolved feature has smaller dimensions than the input

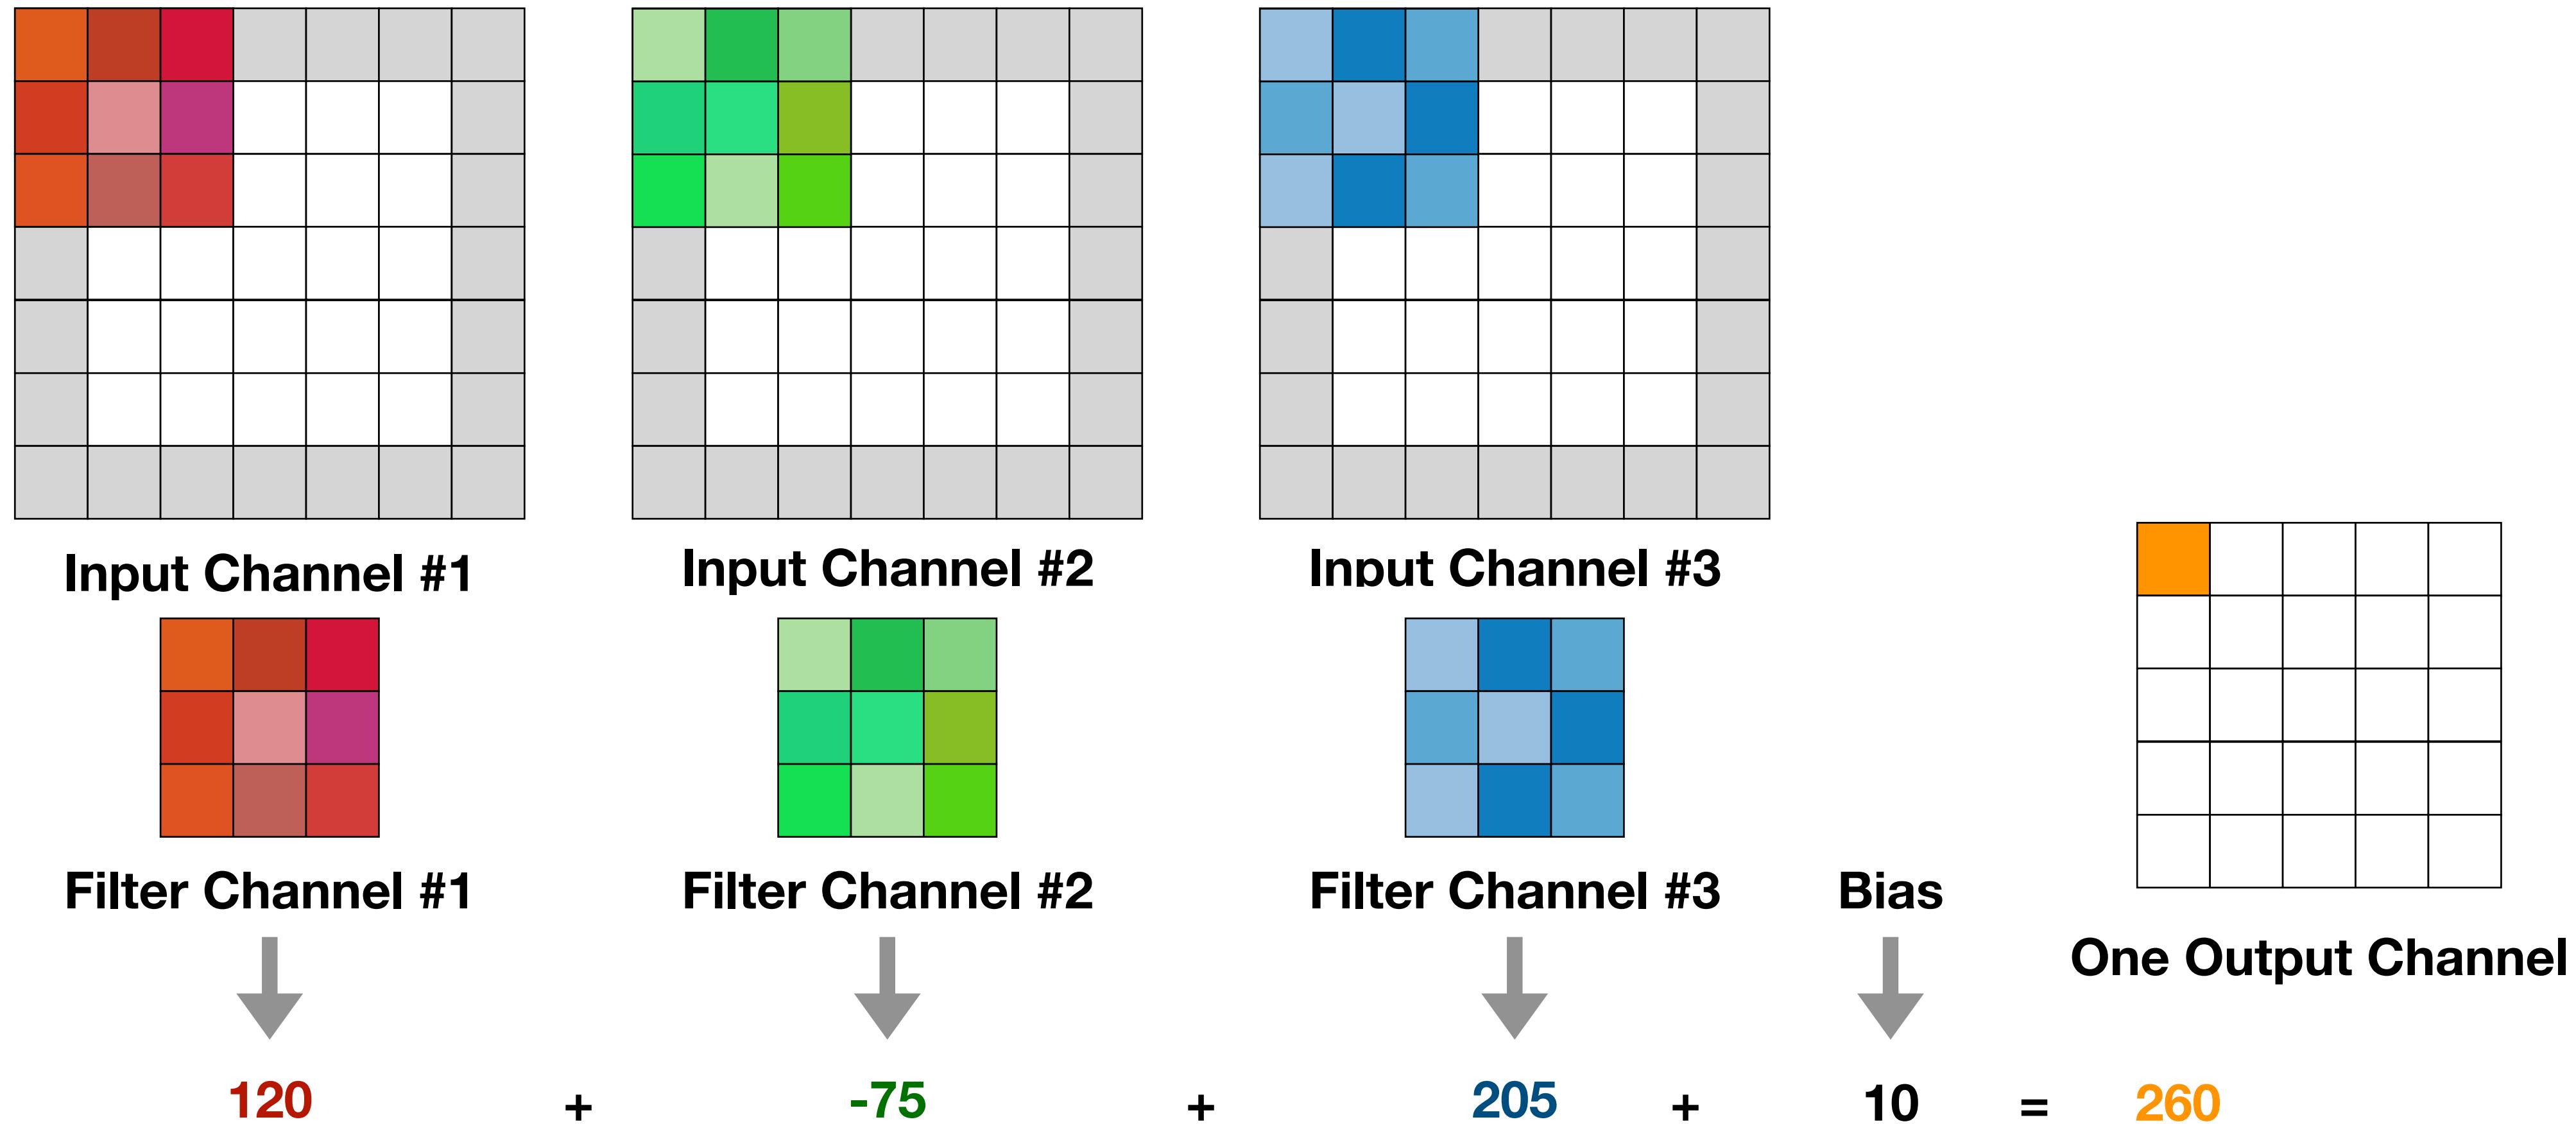

Multiple Channels

It is common to use multiple filters. Each filter is applied to the input image to produce a different result

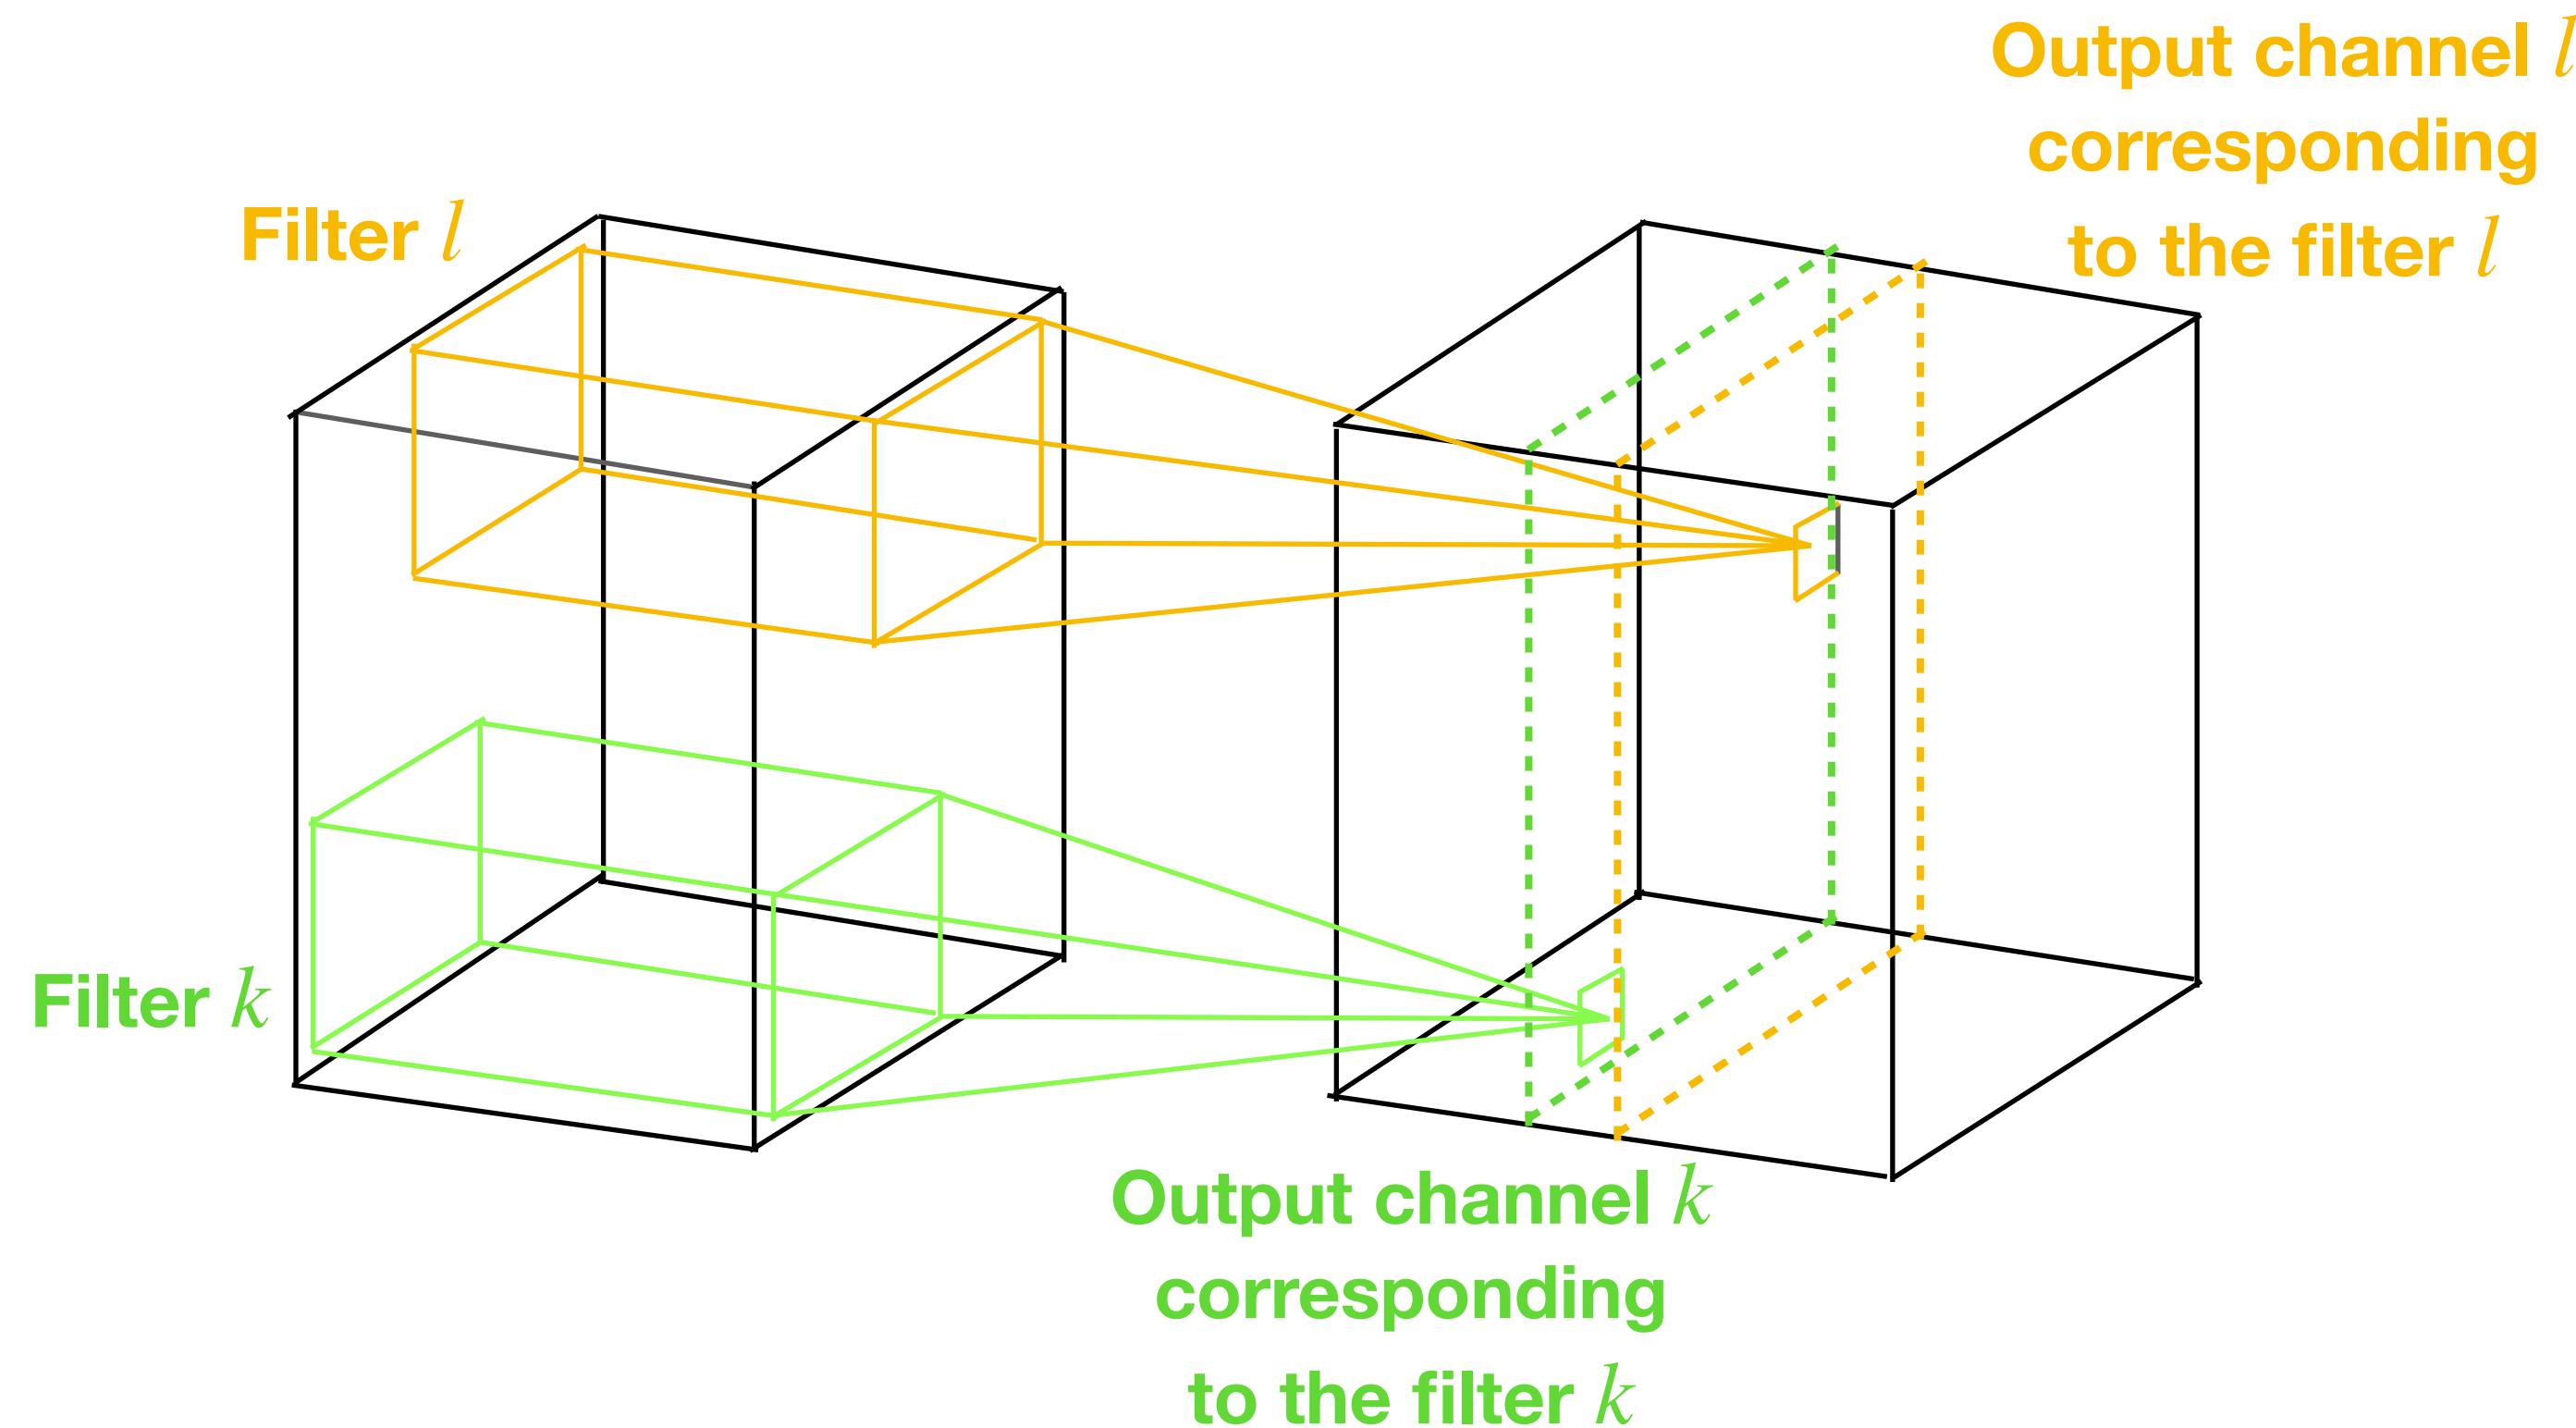

The various outputs from these filters are known as *channels*

Filter for Multi-Channel Convolution

- In the case of images with multiple channels, the filter has the same number of channels as the image input plus a bias term
- The filter channels and the bias are learnable parameters

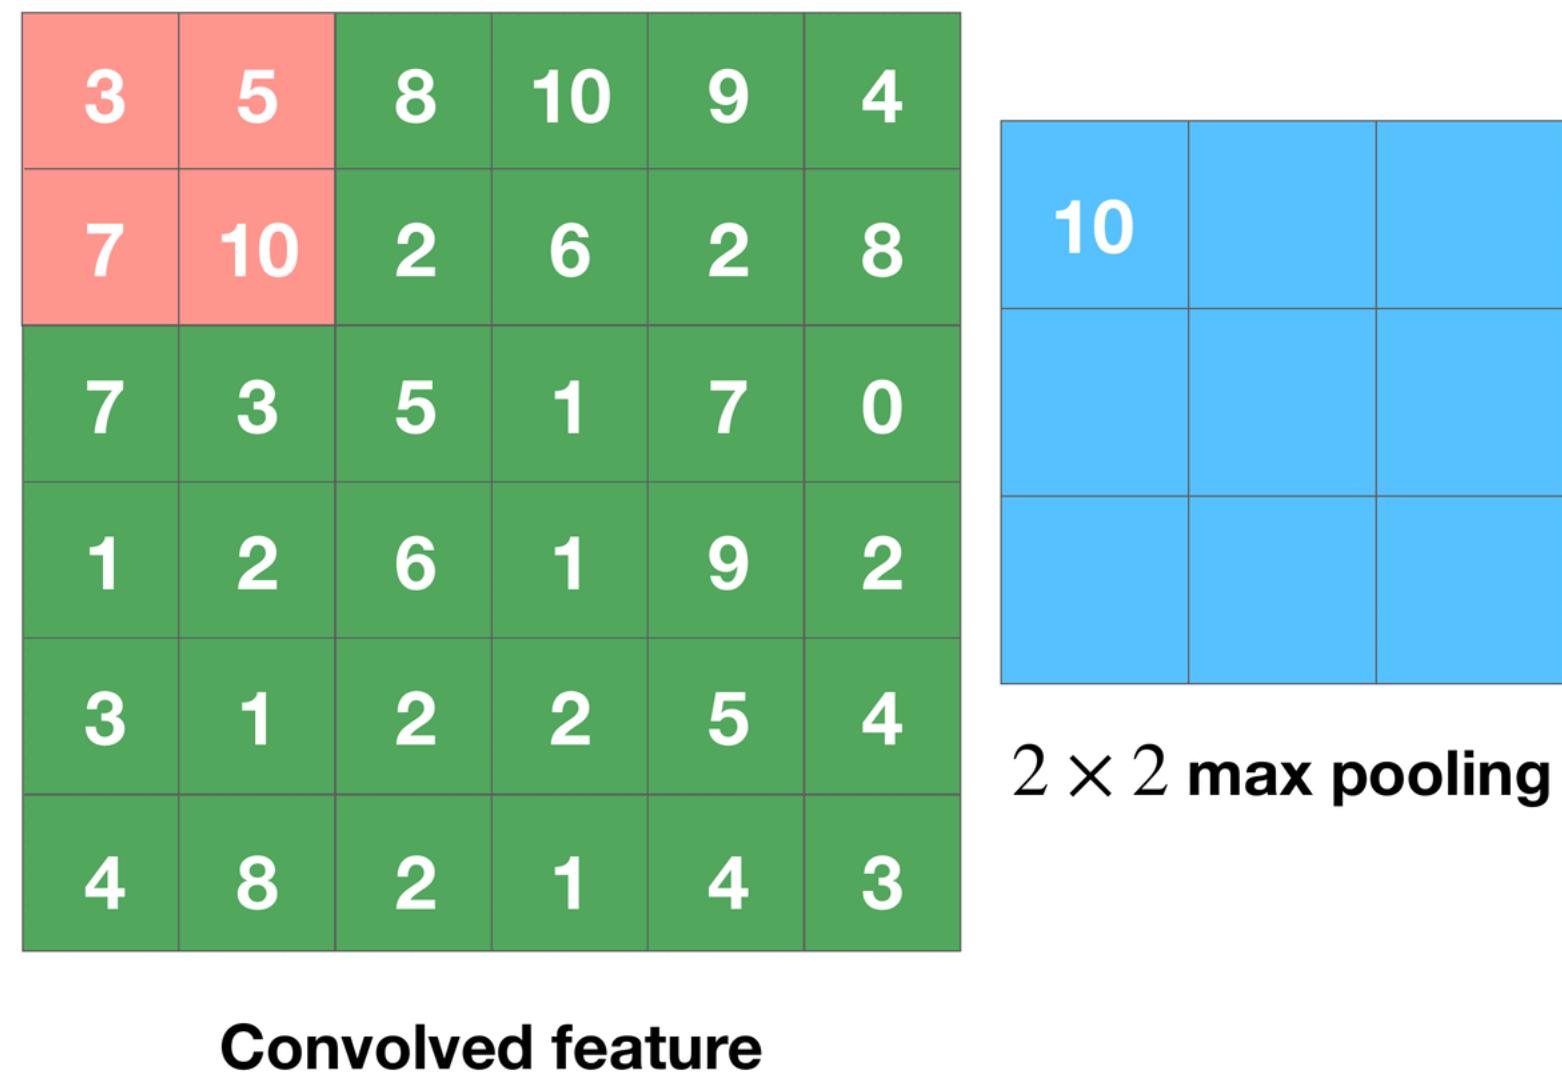

Convolutional Layer

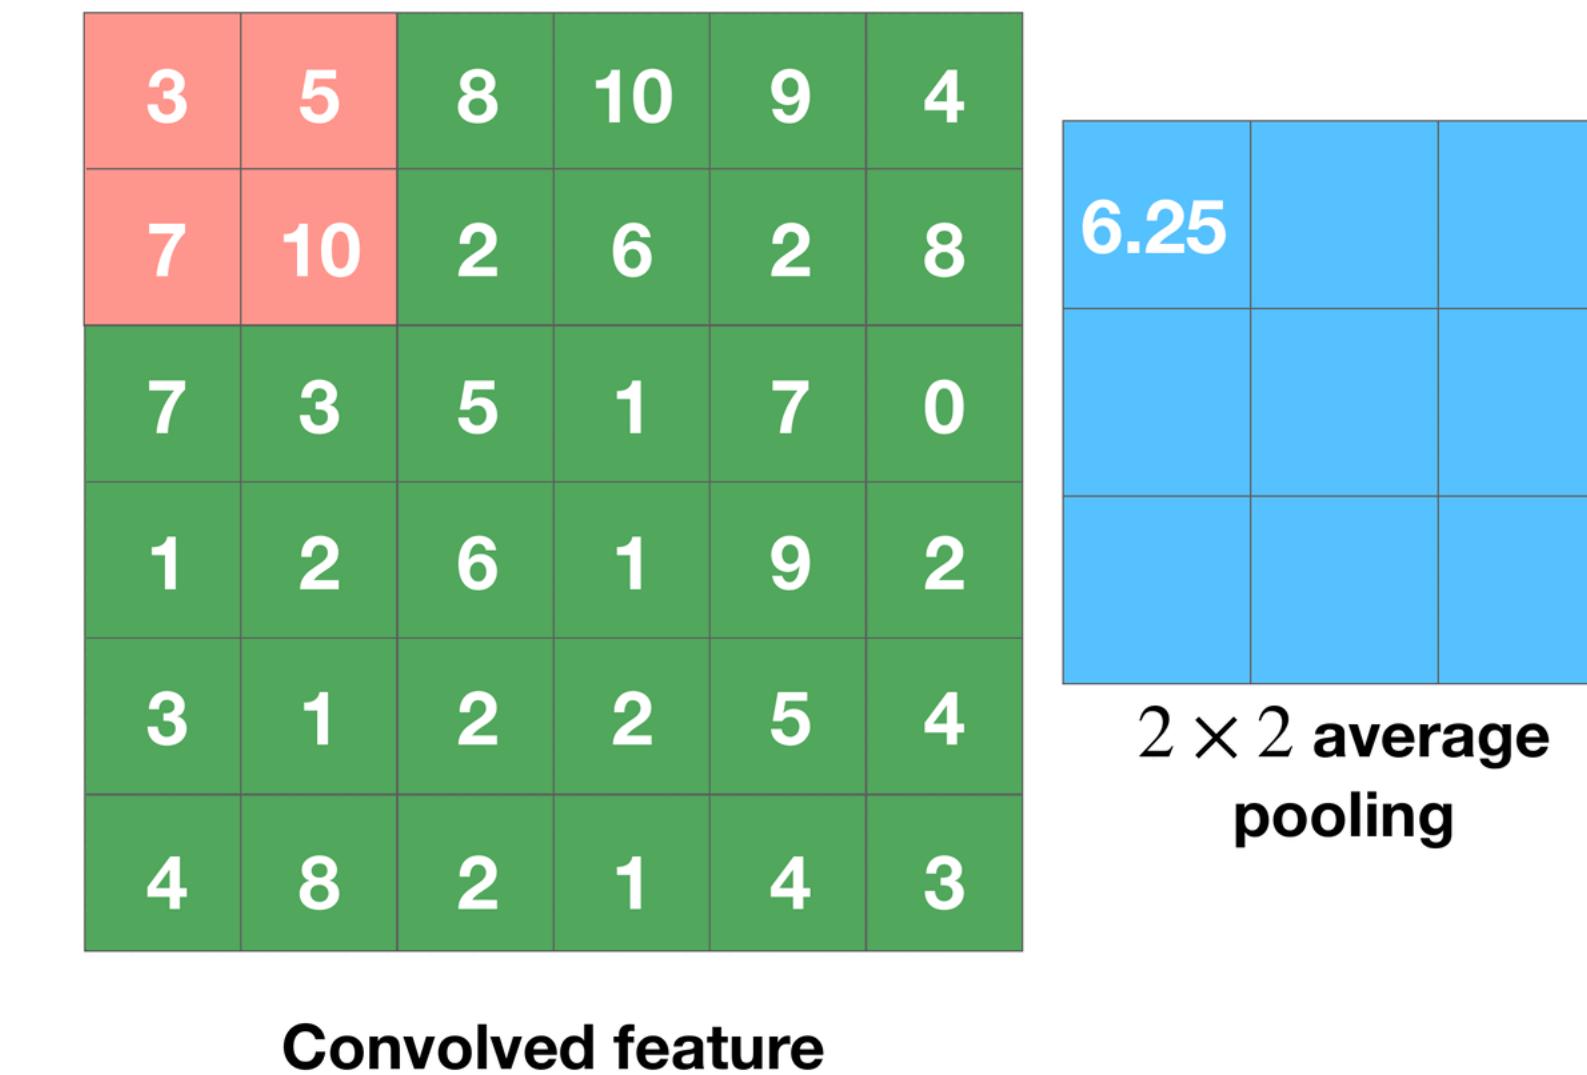

- A convolutional layer is composed of multiple filters
- Each output channel has its own independent filter
- Hyper-parameters of the convolutional layer: size, padding, stride

Pooling: often applied after the convolutional layer

Max pooling: returns the maximum value of the portion of the convolved feature that is covered by the kernel

Average pooling: returns the average value of the portion of the convolved feature that is covered by the kernel

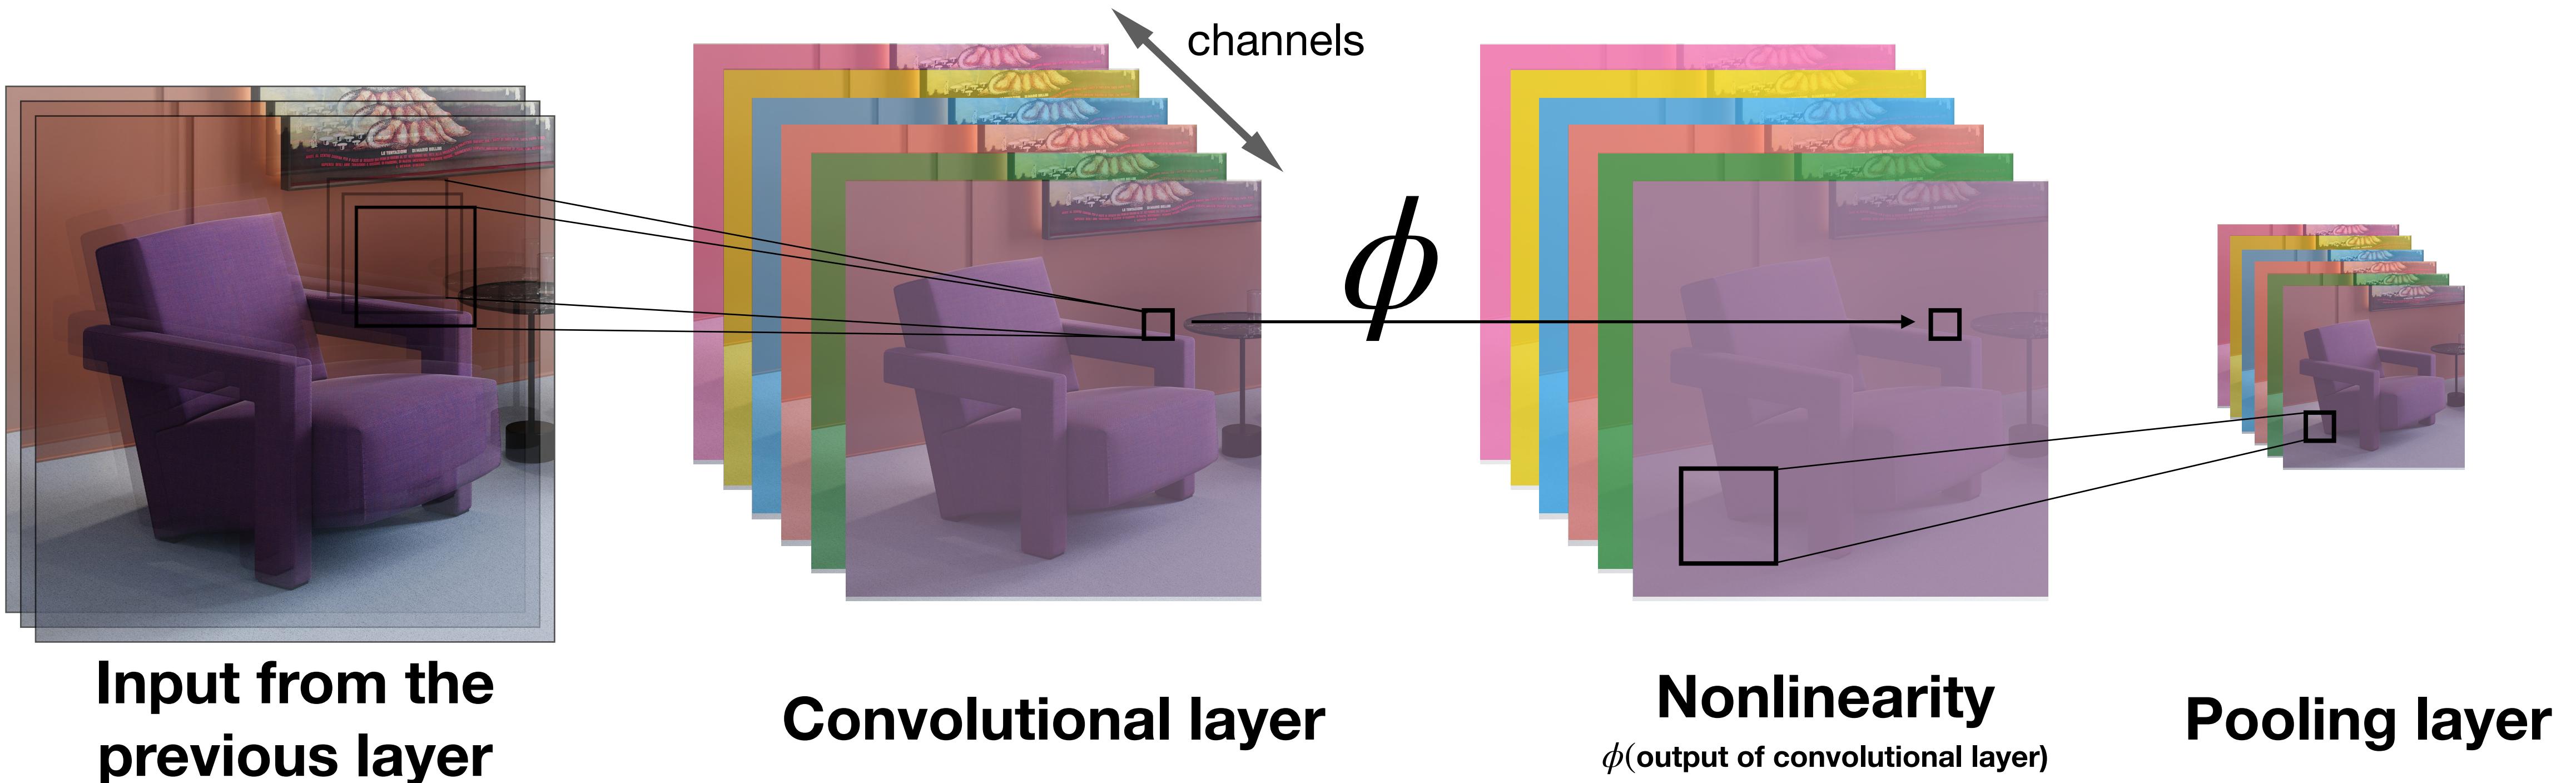

Pooling is a downsampling operation that reduces the spatial dimensions of the convolved feature

Remark: Pooling layers do not have learnable parameters

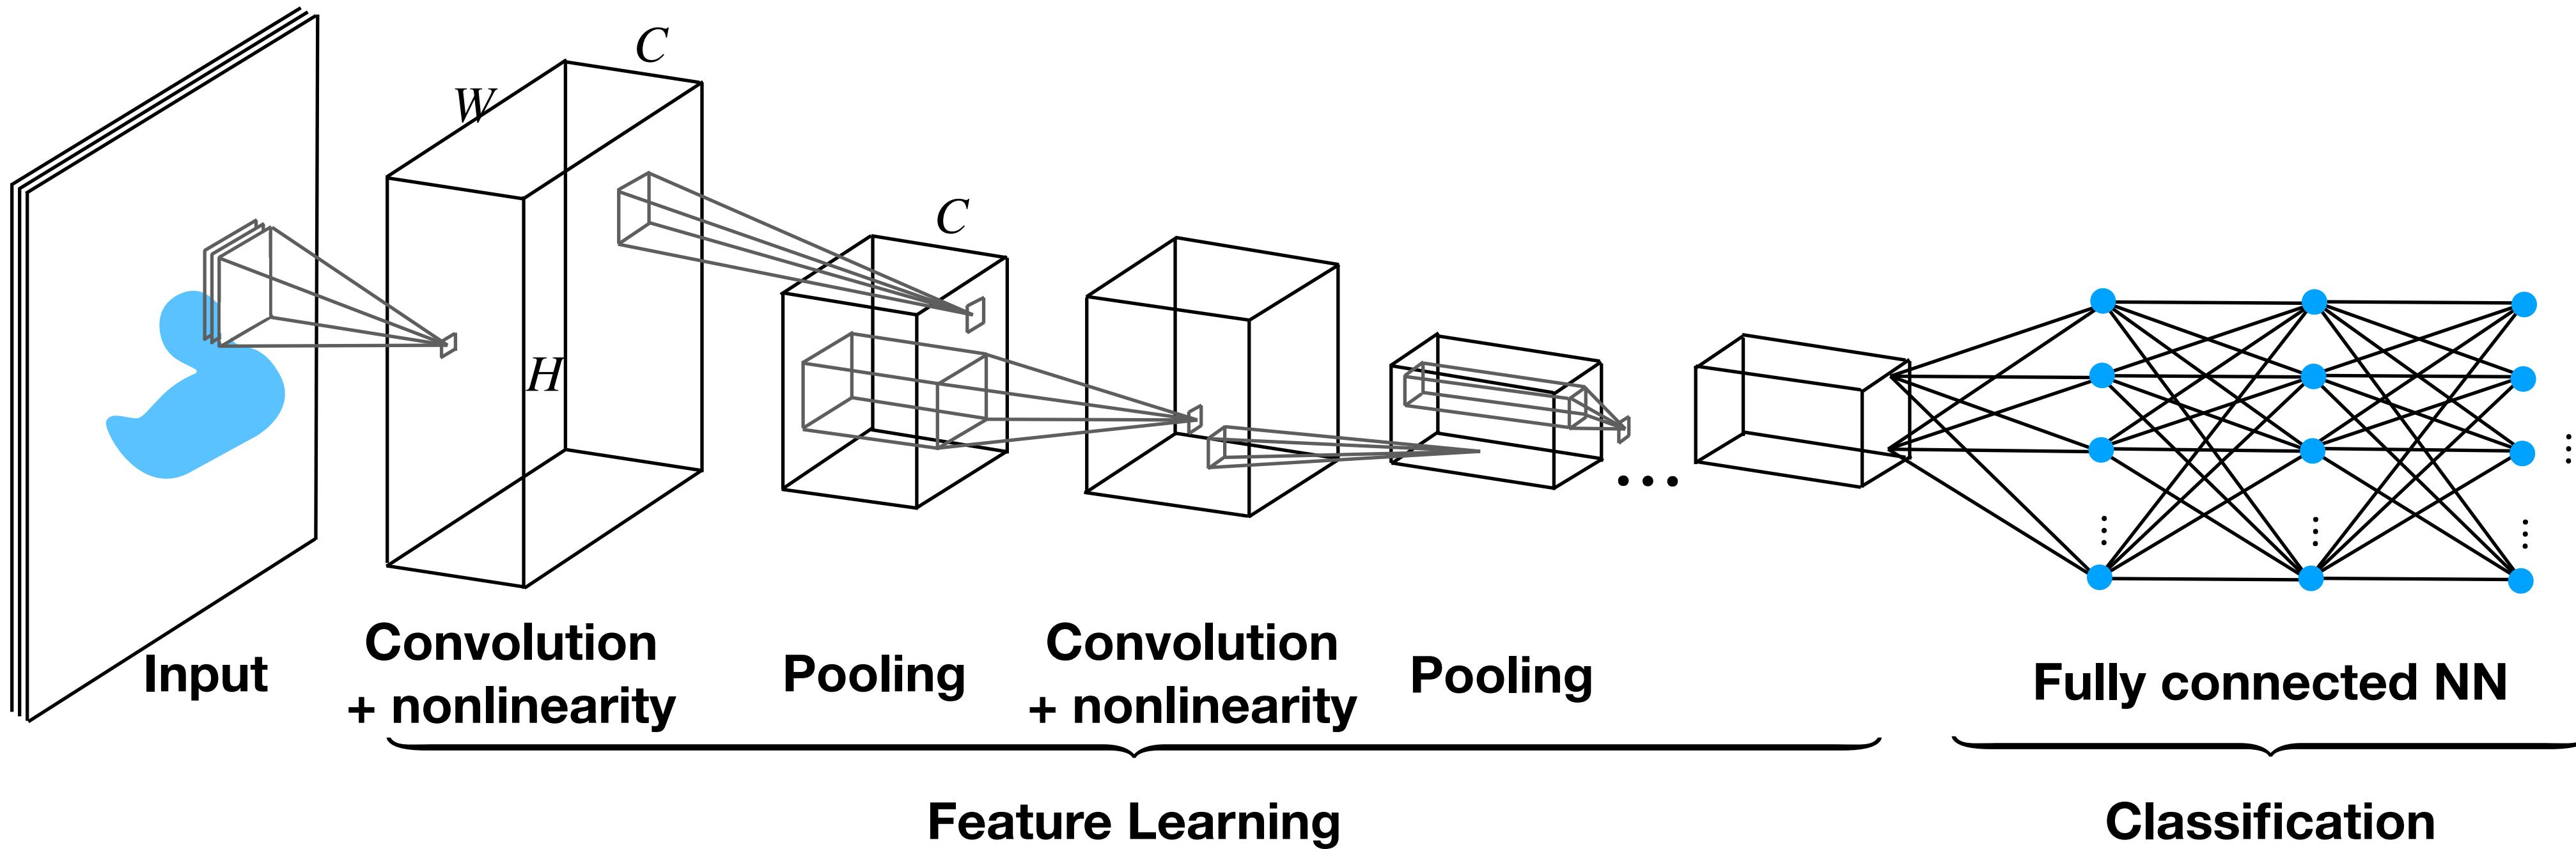

Hyperparameters are the size, type, and stride of the pooling operation

Non-linearity and convolutional NNs

Important: A non-linearity such as ReLU is included after each convolutional layer to make the model non-linear

Convolutional NNs: General Structure

Receptive field (area of input that affects a given neuron) increases with depth:

- First layers extract low-level features, e.g., edges, colors
 - Subsequent layers extract high-level features, e.g., objects
- ConvNet reduces the images to a form easier to process without losing essential features

Backpropagation with weight sharing

Weight sharing is used in CNN: many edges use the same weights

Training:

1. Run backpropagation as if the weights were not shared (treat each weight as an independent variable)
2. Once the gradient is computed, sum the gradients of all edges that share the same weight

Why: let $f(x, y, z) : \mathbb{R}^3 \rightarrow \mathbb{R}$ and $g(x, y) = f(x, y, x)$

$$\left(\frac{\partial g}{\partial x}(x, y), \frac{\partial g}{\partial y}(x, y) \right) = \left(\frac{\partial f}{\partial x}(x, y, x) + \frac{\partial f}{\partial z}(x, y, x), \frac{\partial f}{\partial y}(x, y, x) \right)$$

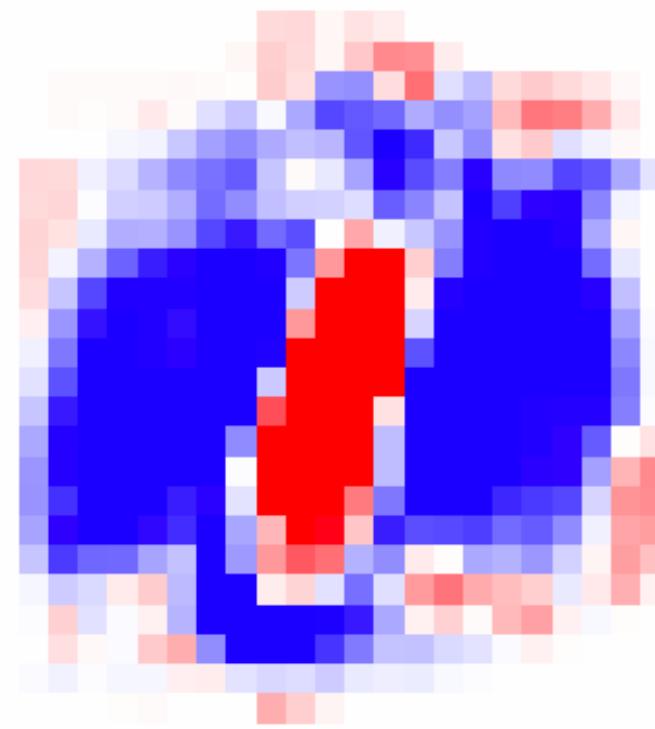

Chain rule

What do ConvNets learn?

Learned Convolutional Filters on MNIST

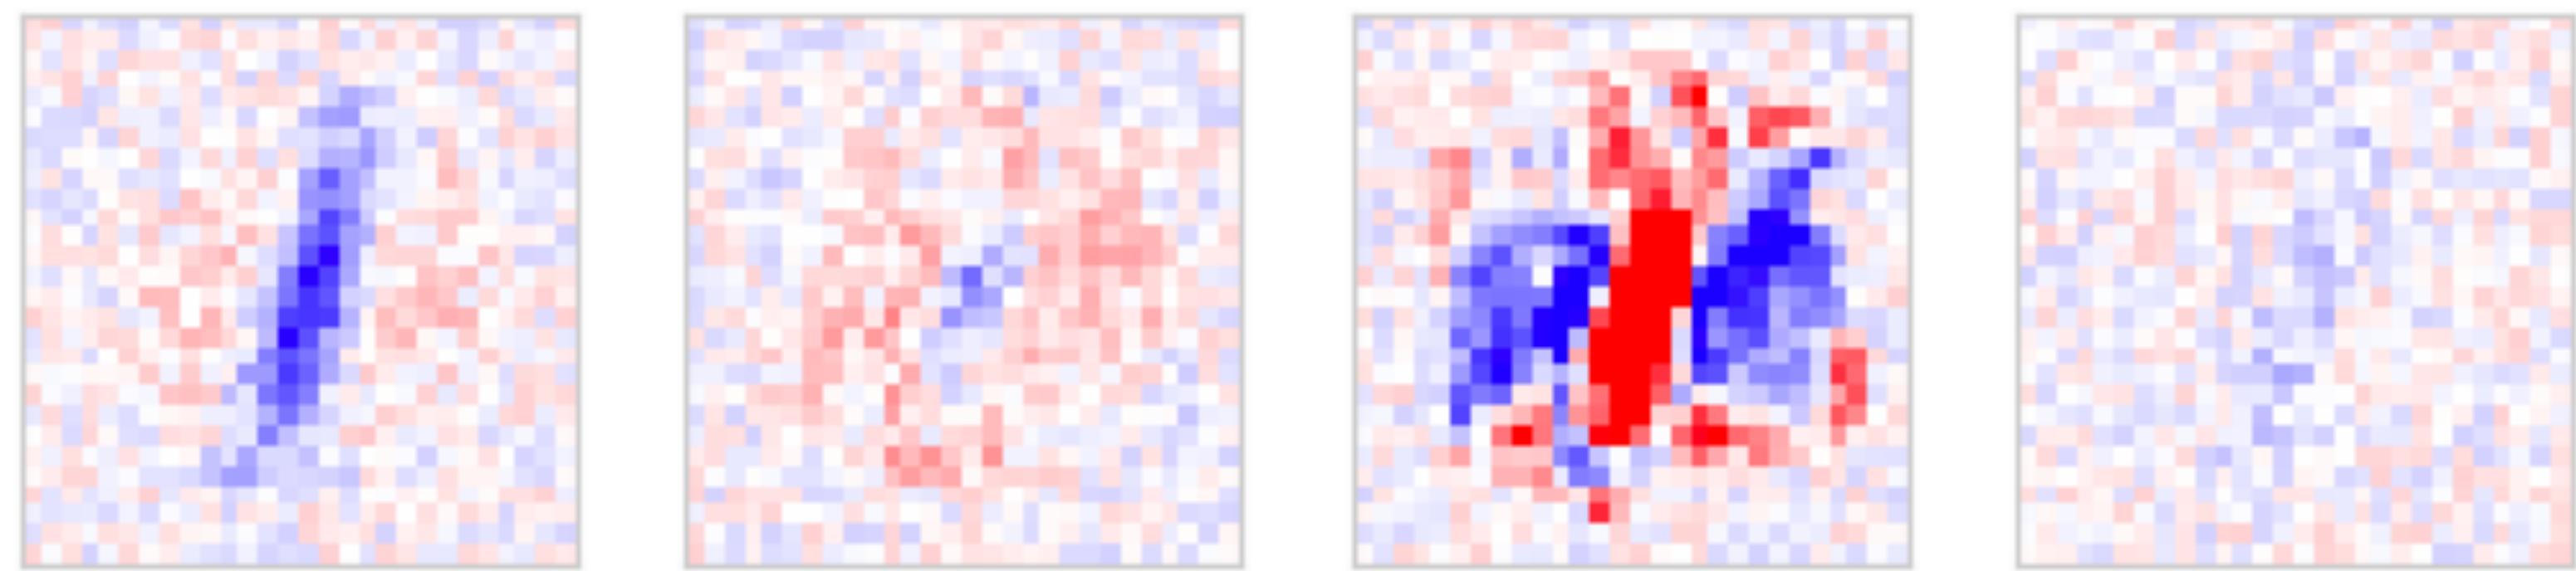

Linear model

parameter vector w

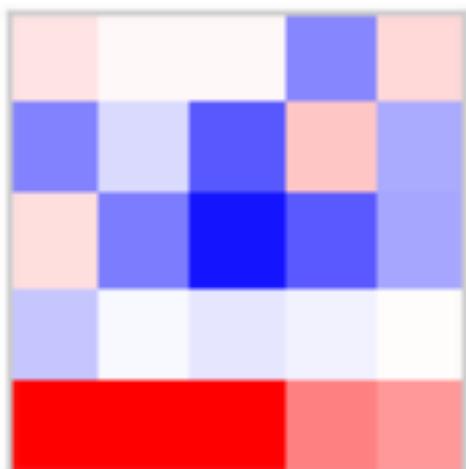

Fully-connected network

first-layer vector $w_{:,1}$ first-layer vector $w_{:,2}$ first-layer vector $w_{:,3}$ first-layer vector $w_{:,4}$

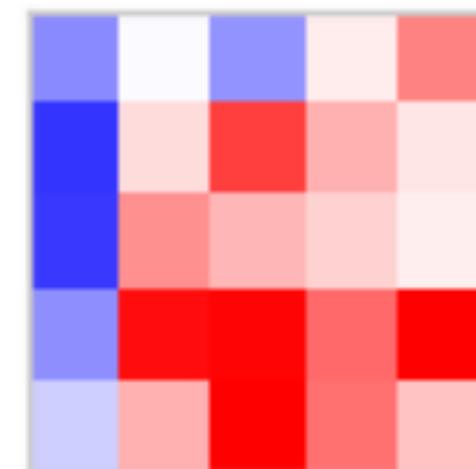

Convolutional networks

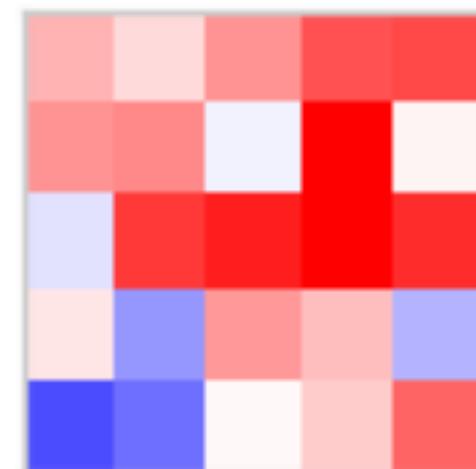

filter $f^{(1)}$

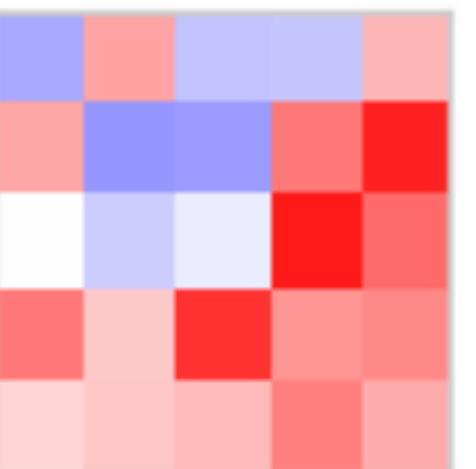

filter $f^{(2)}$

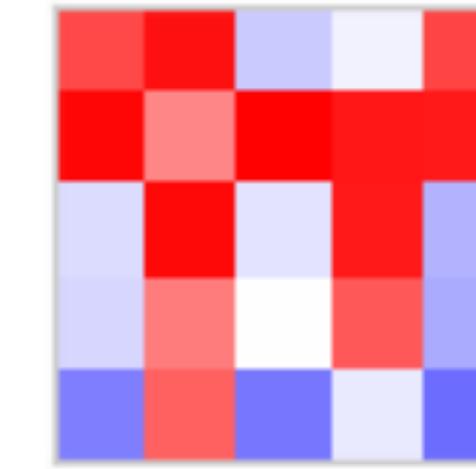

filter $f^{(3)}$

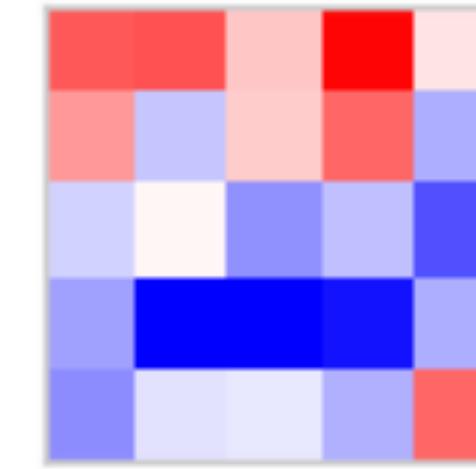

filter $f^{(4)}$

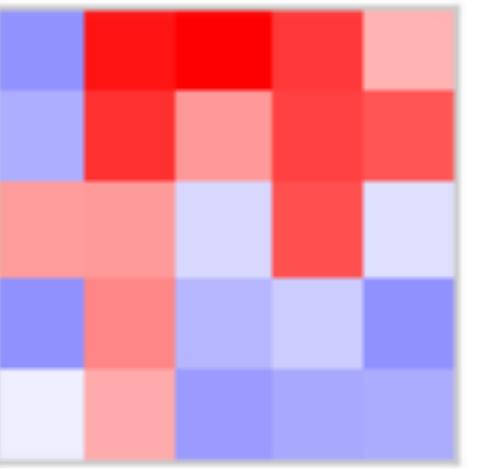

filter $f^{(5)}$

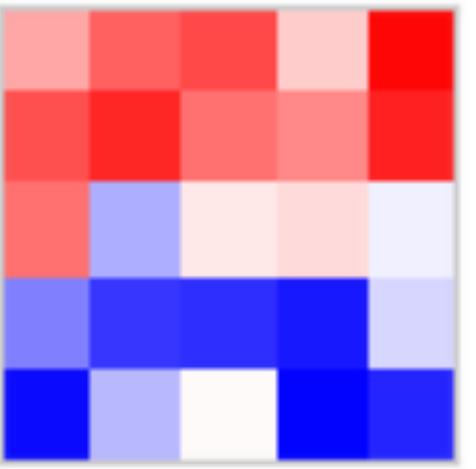

filter $f^{(6)}$

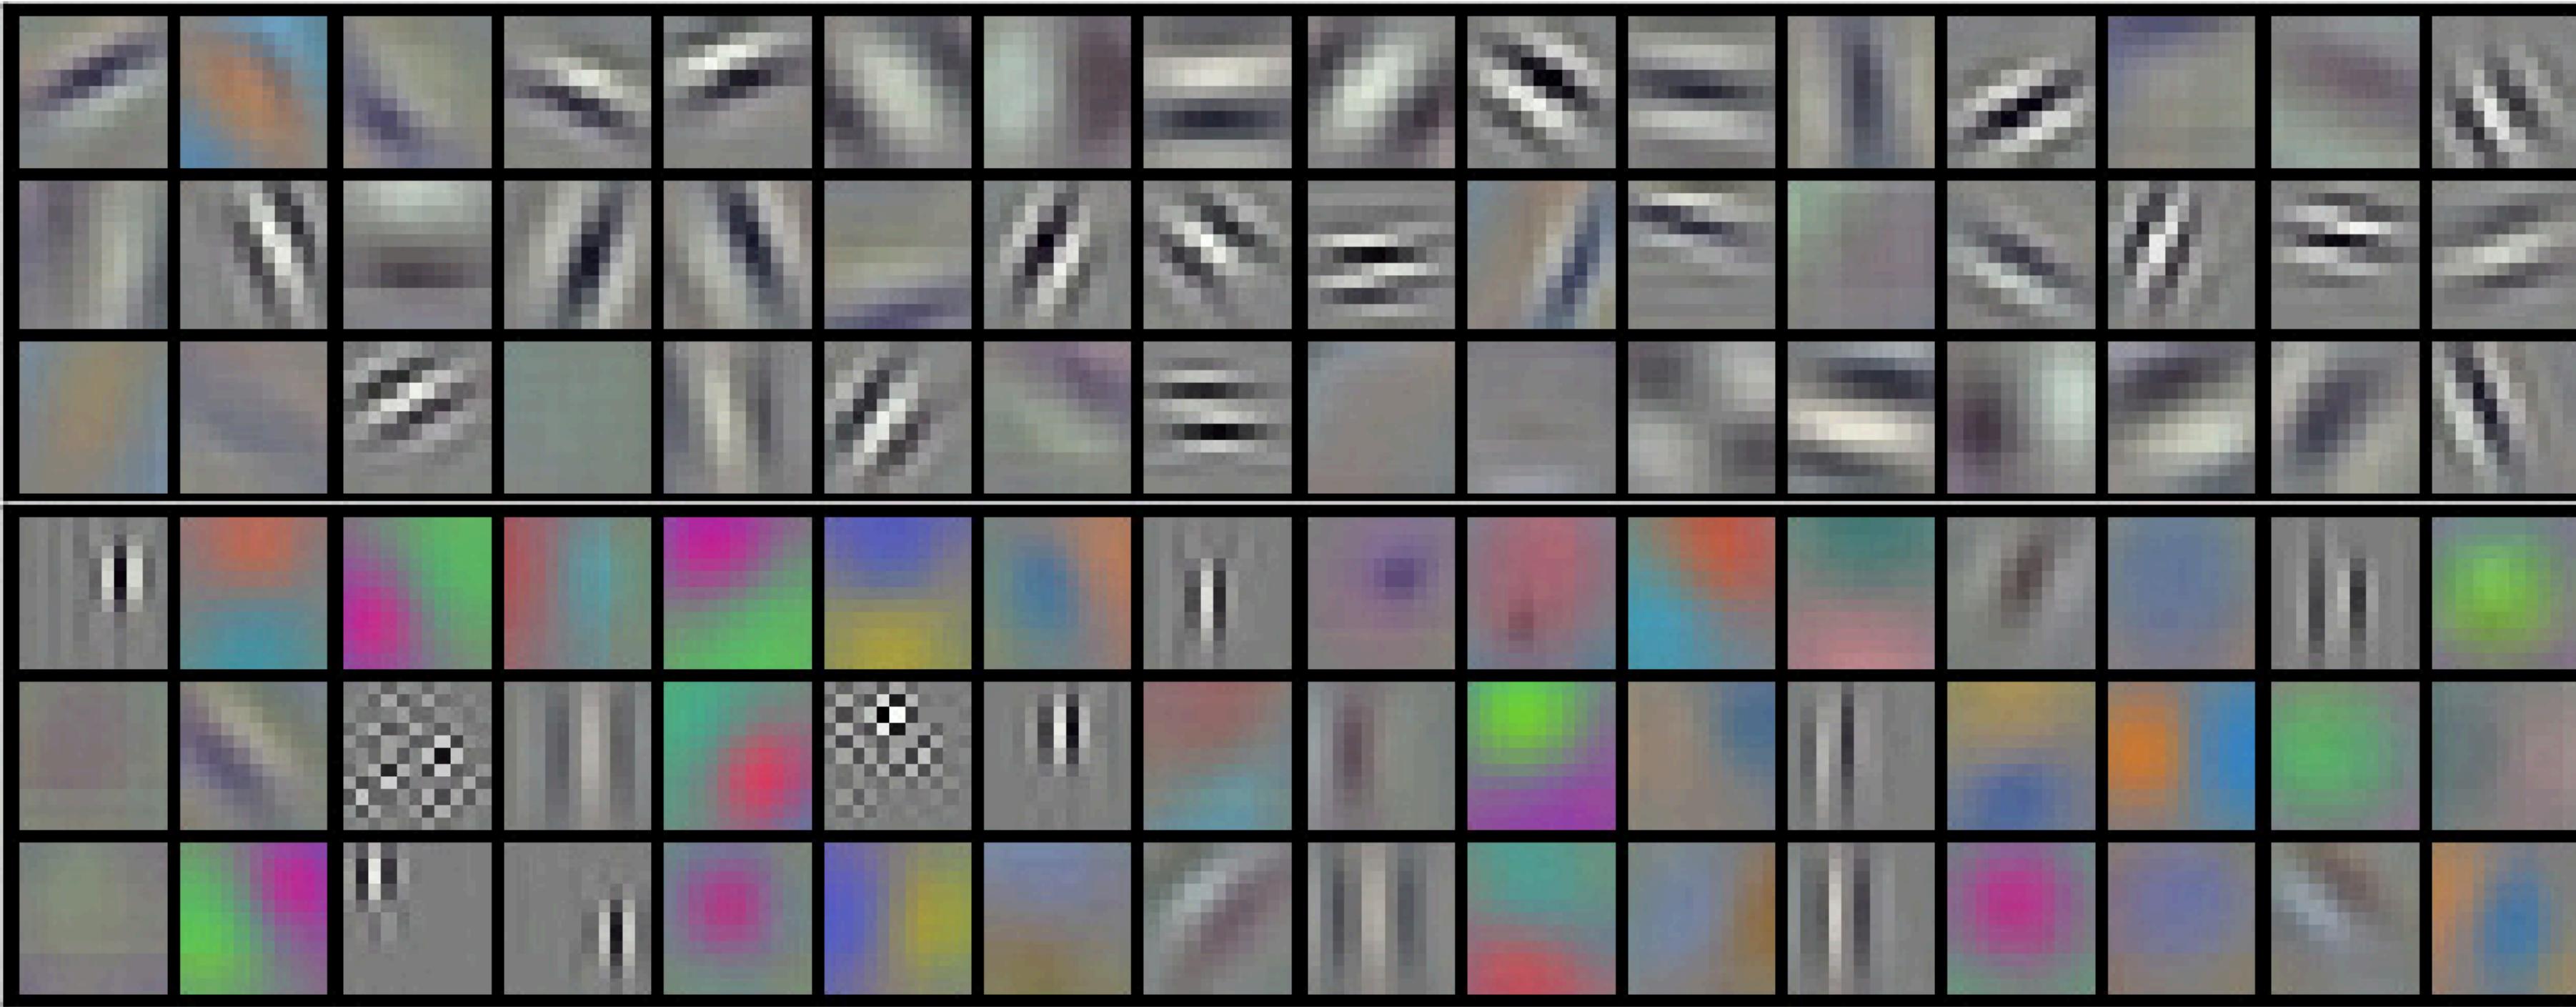

filter $f^{(7)}$

filter $f^{(8)}$

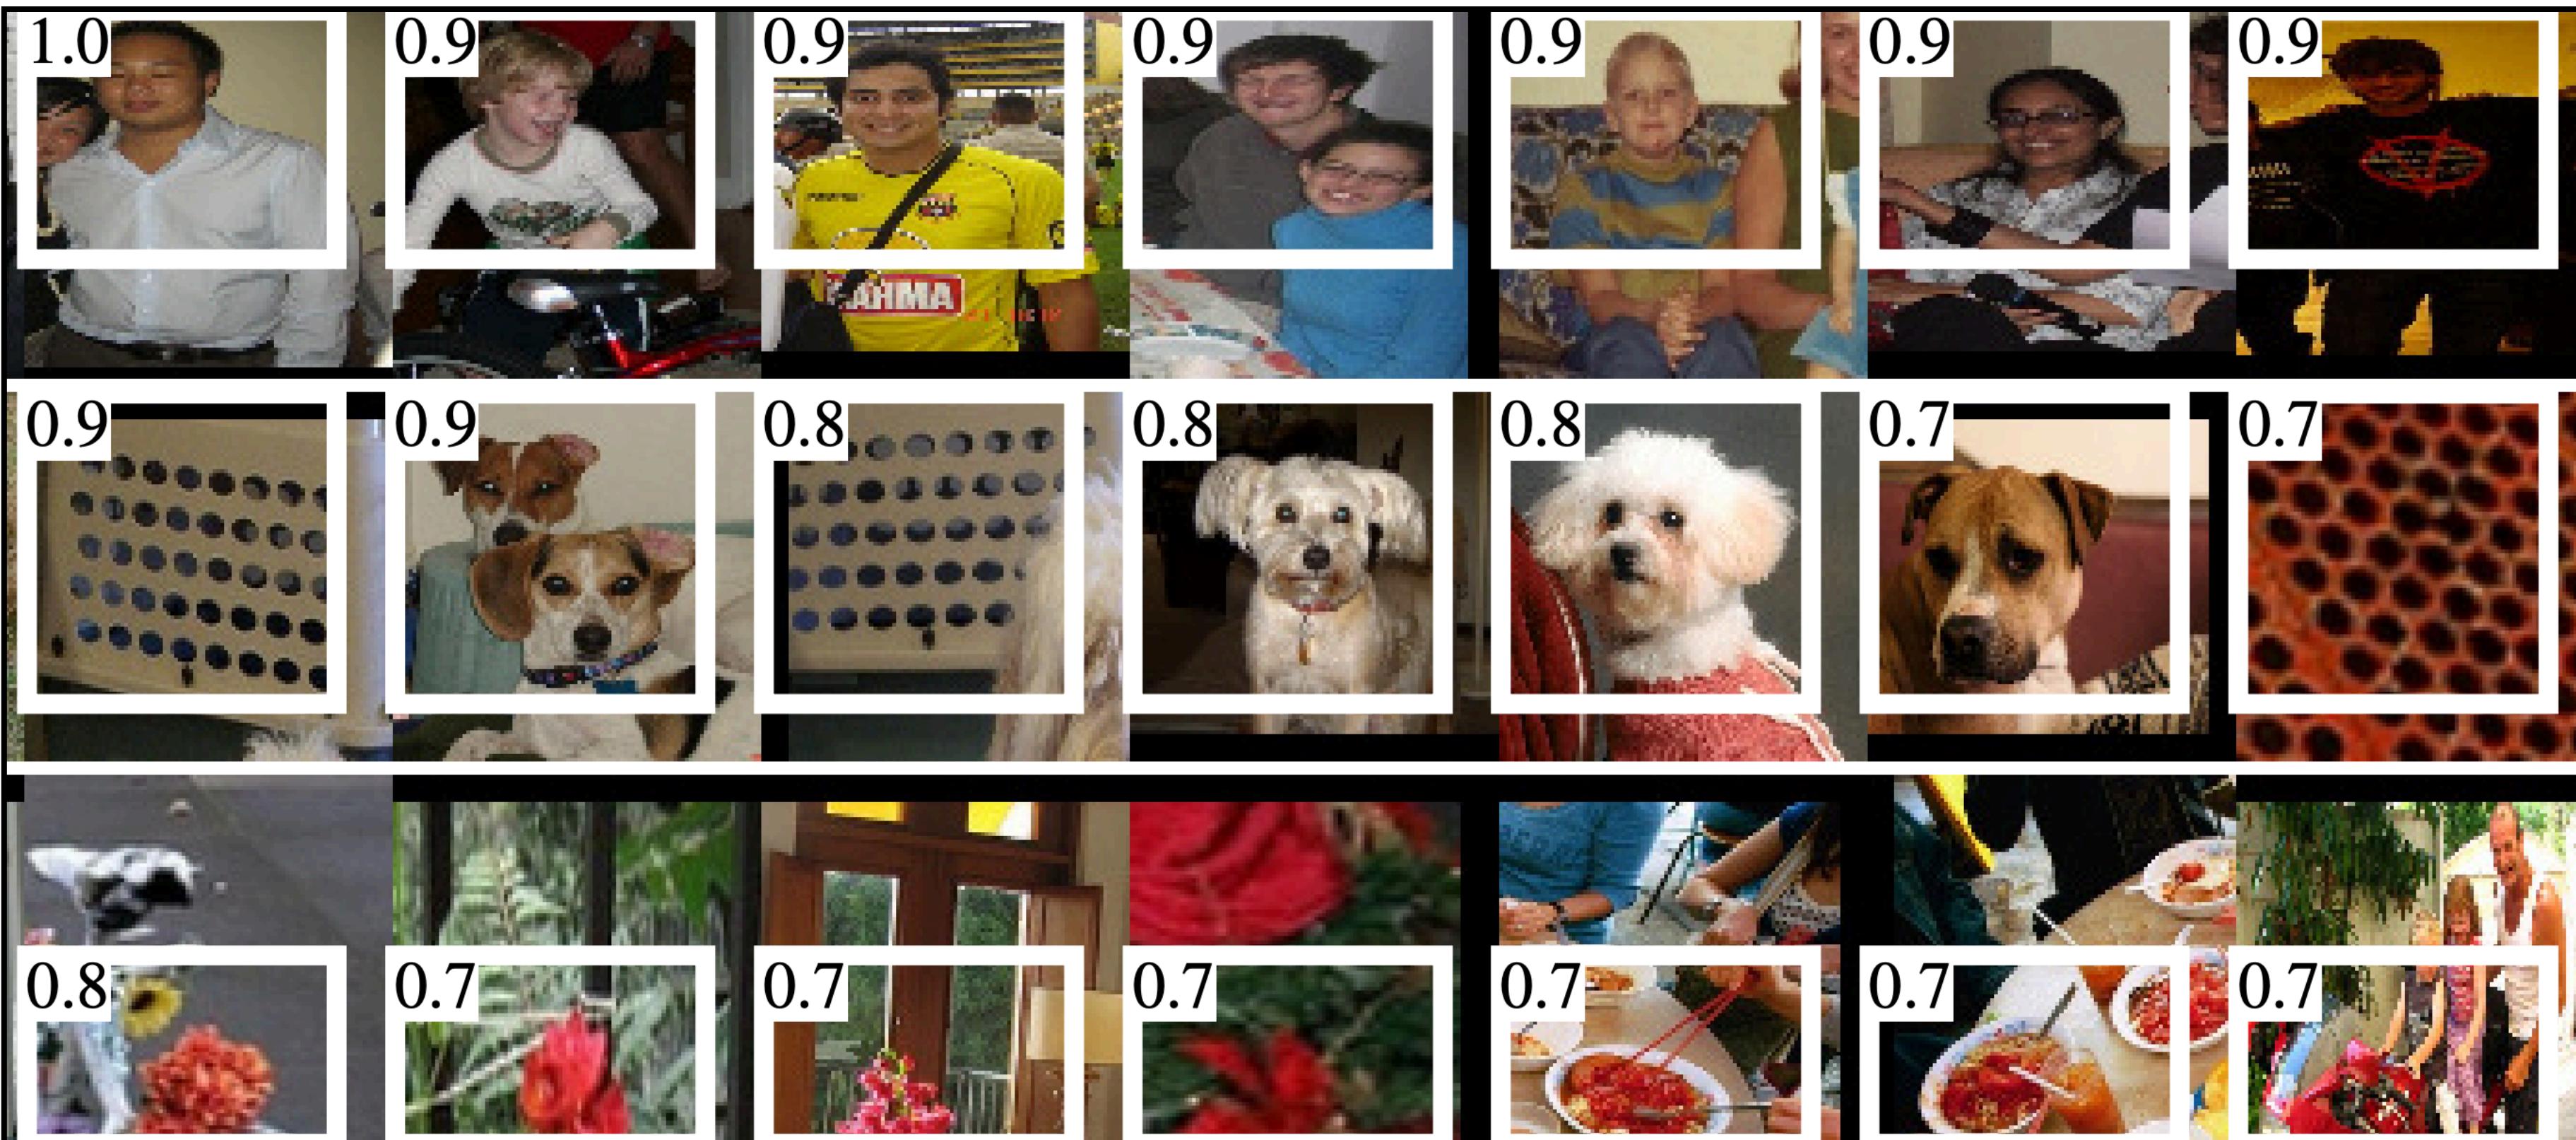

Learned Convolutional Filters on ImageNet

Source: [ImageNet Classification with Deep Convolutional Neural Networks \(NeurIPS 2012\)](#)

- Filters of the **first** layer can be interpretable
- Edge and color detectors typically emerge when trained on large datasets

Individual Activations Can Be Interpretable

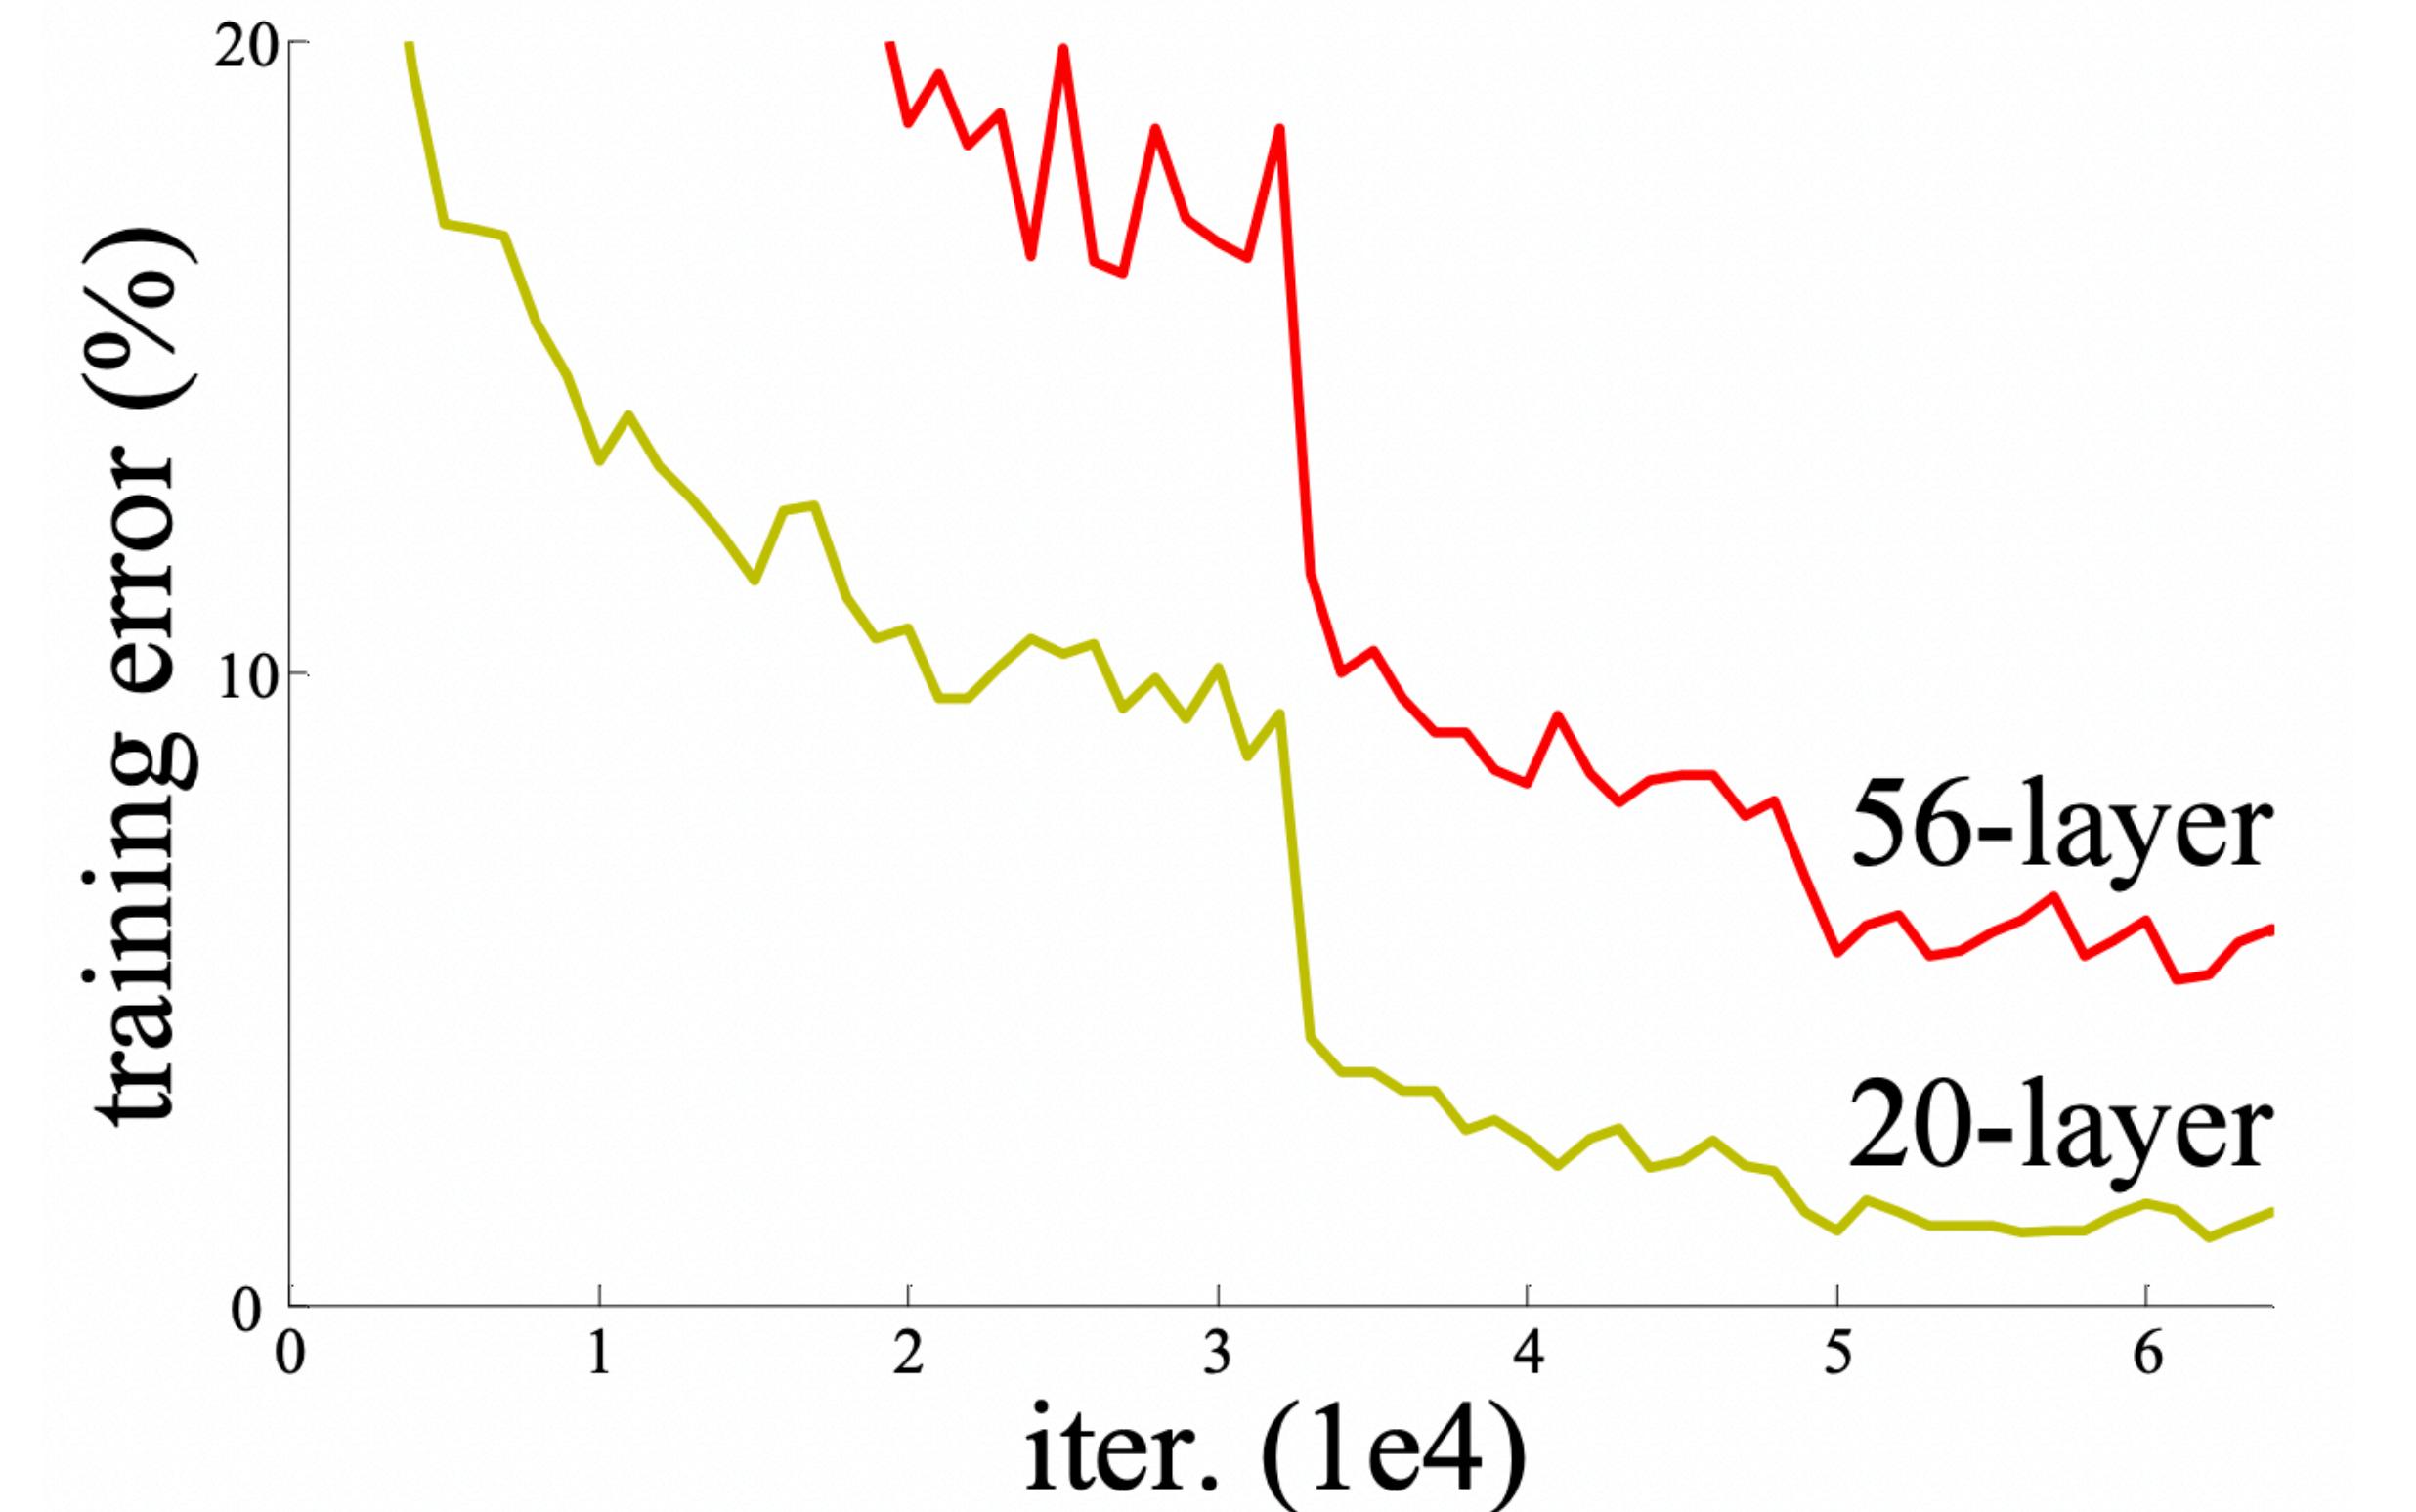

Source: [Rich feature hierarchies for accurate object detection and semantic segmentation](#) (CVPR 2014)

- Receptive fields and activation values are drawn in white
- Each activation detects some **pattern** or **object** (not always interpretable)
- Activations in later layers detect more complex patterns

Residual Networks

Skip Connections and Residuals

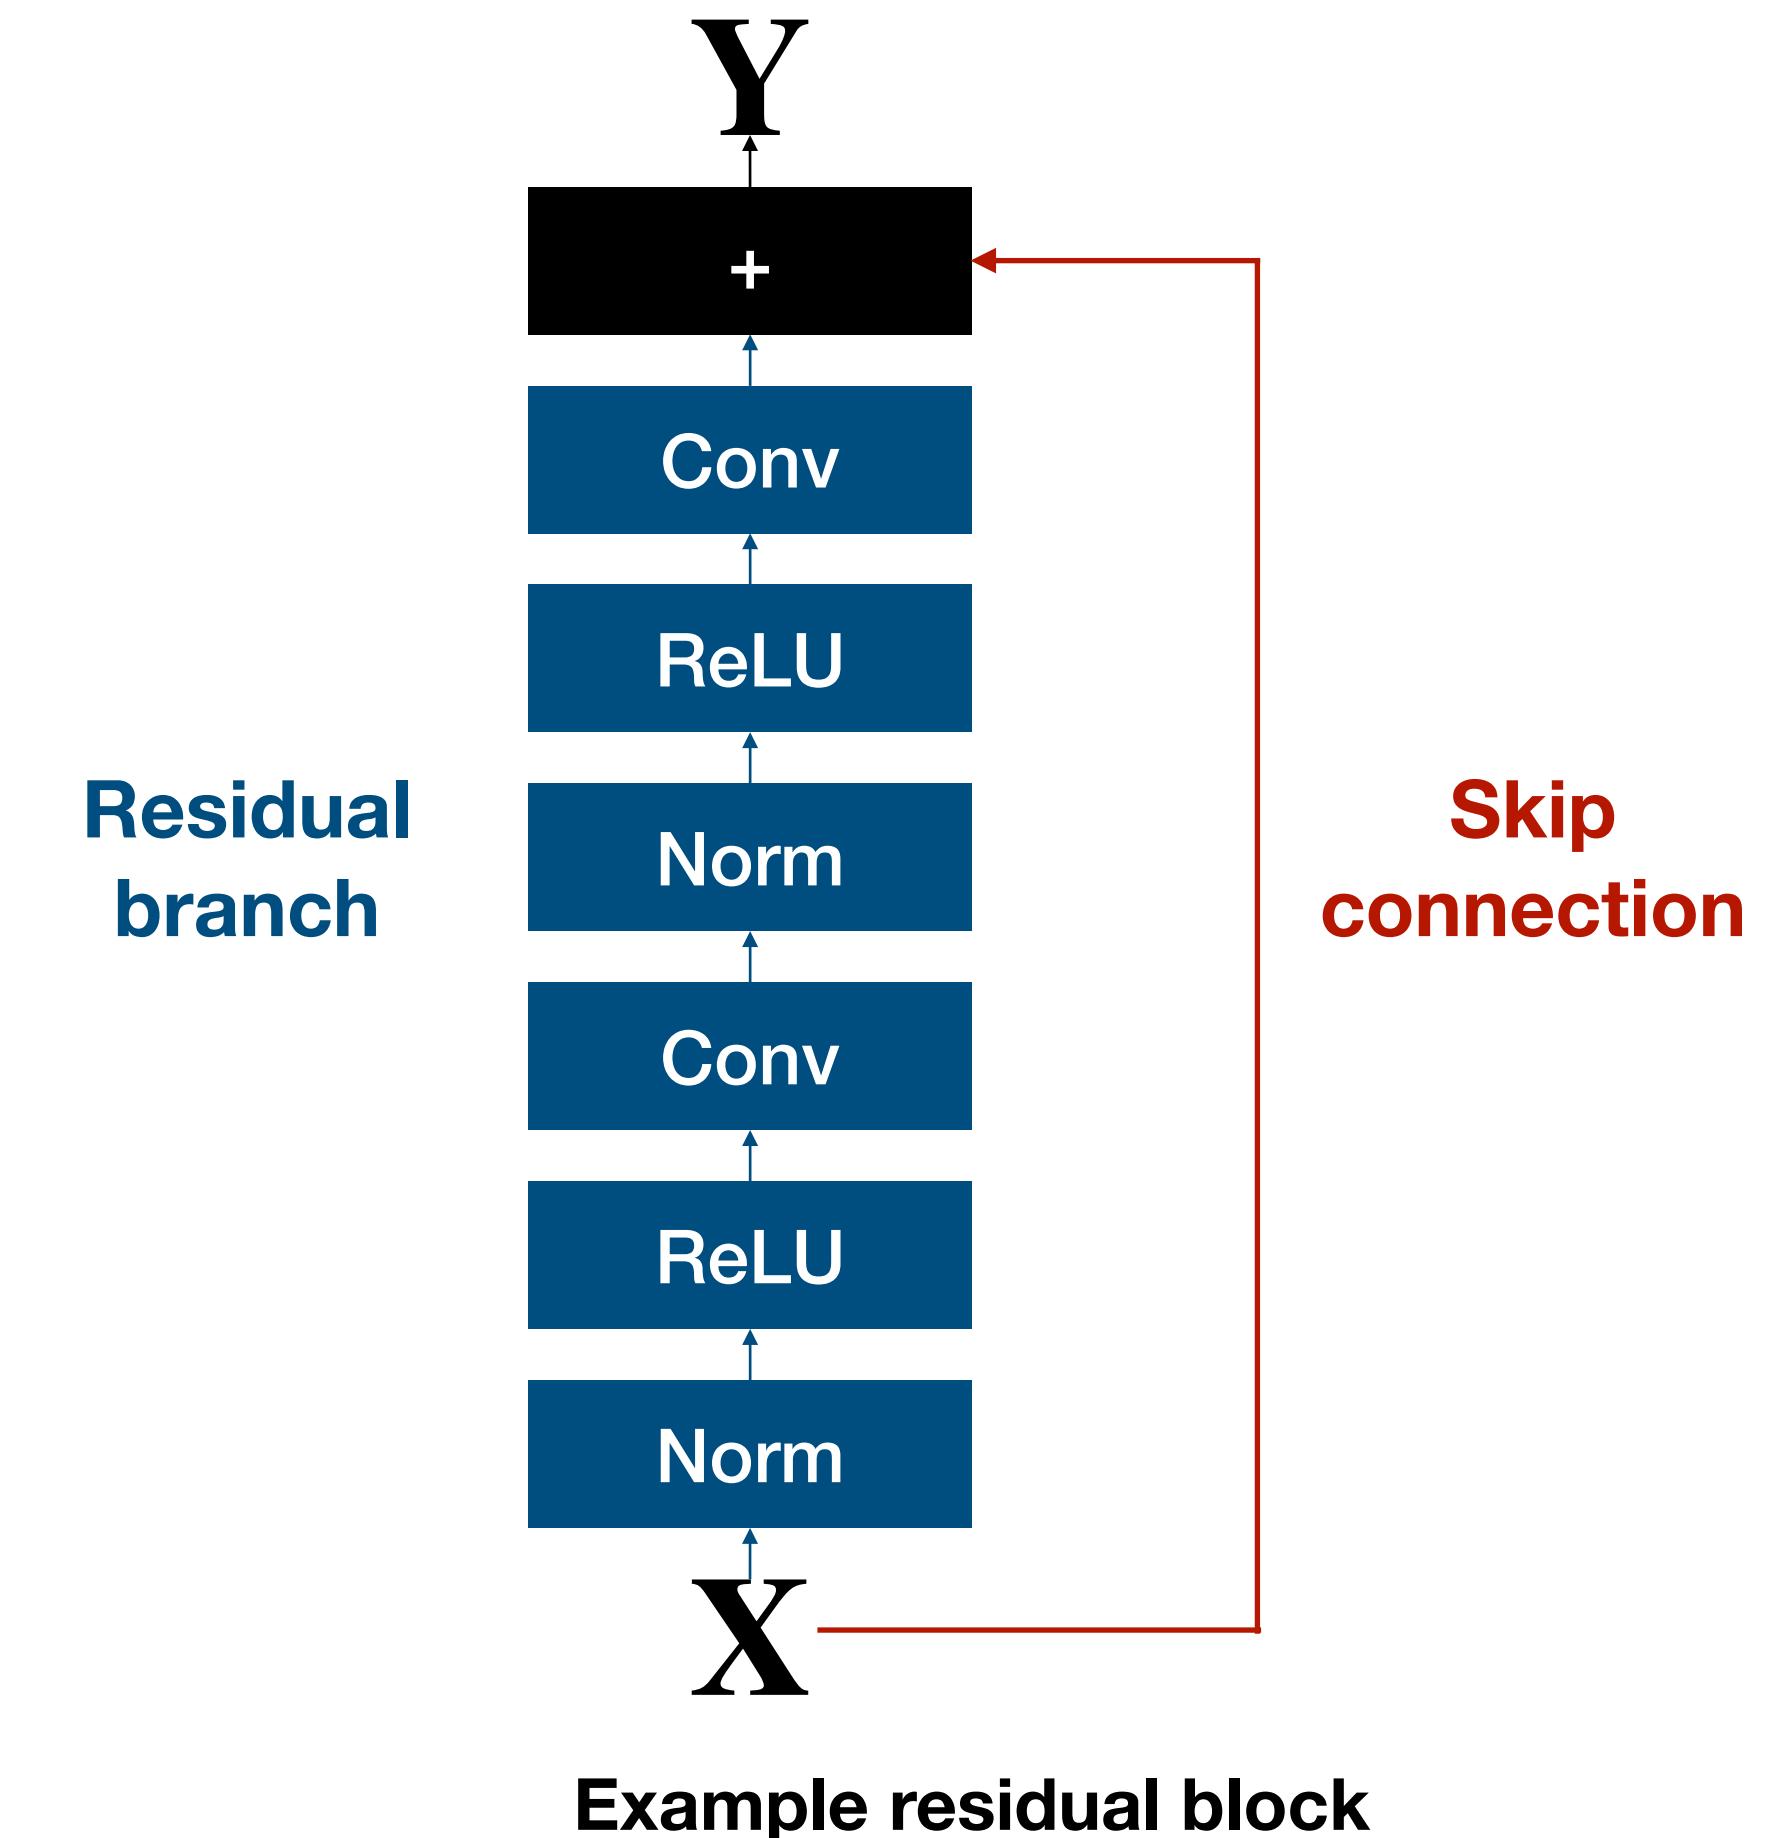

- **Starting point:** Adding more layers should lead to the same or lower training loss as they can learn the identity function
- **ResNet paper** indicates that this is not always the case
- **Solution:** add a *skip connection* around some layers $F(\mathbf{X})$
- **Standard network:** $\mathbf{Y} = F(\mathbf{X})$
- **Residual network:** $\mathbf{Y} = R(\mathbf{X}) + \mathbf{X}$ where $R(\mathbf{X})$ is called a residual branch

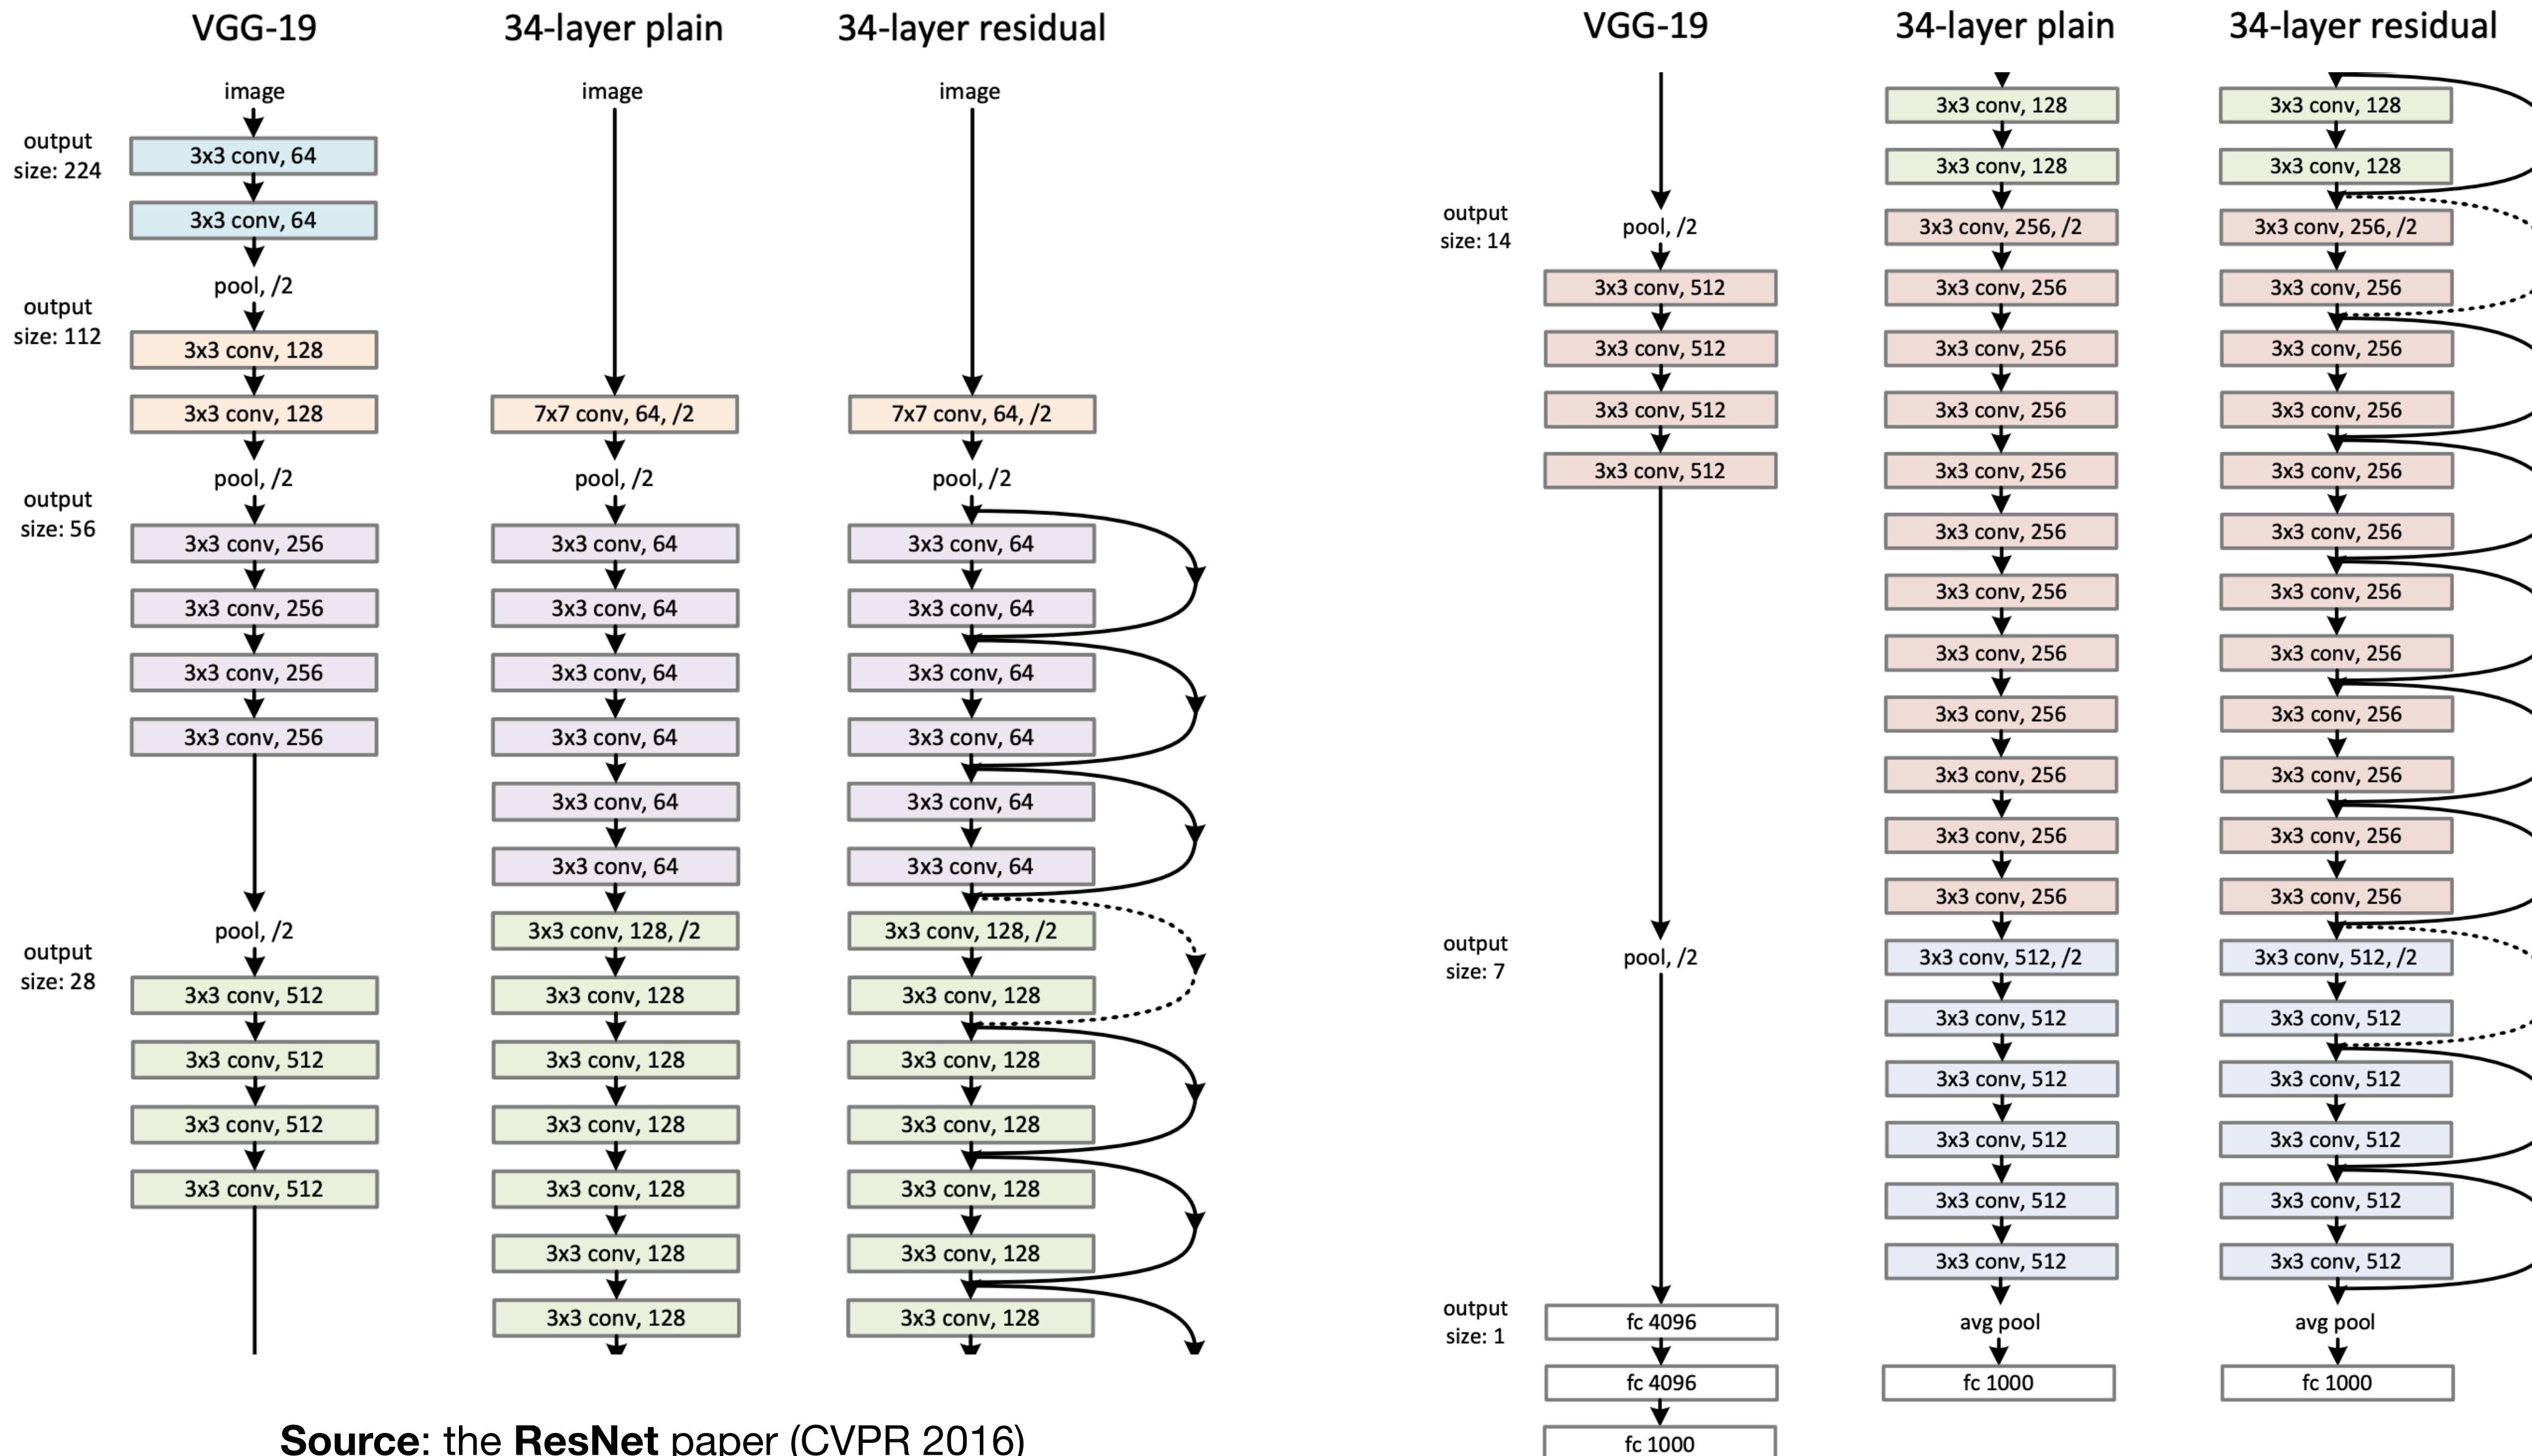

Observation from the **ResNet paper**: deeper CNNs are harder to train

Skip Connections and Residuals

- **Example of $R(\mathbf{X})$:** see on the right
- **Technical detail:** If $\text{size}(\mathbf{Y}) \neq \text{size}(\mathbf{X})$, additional operations are needed on the skip connection to match the dimensions
- Skip connections address the observed convergence issue, making the training of very deep networks (with hundreds of layers) feasible
- Skip connections are used in almost all modern neural networks (including CNNs and transformers)

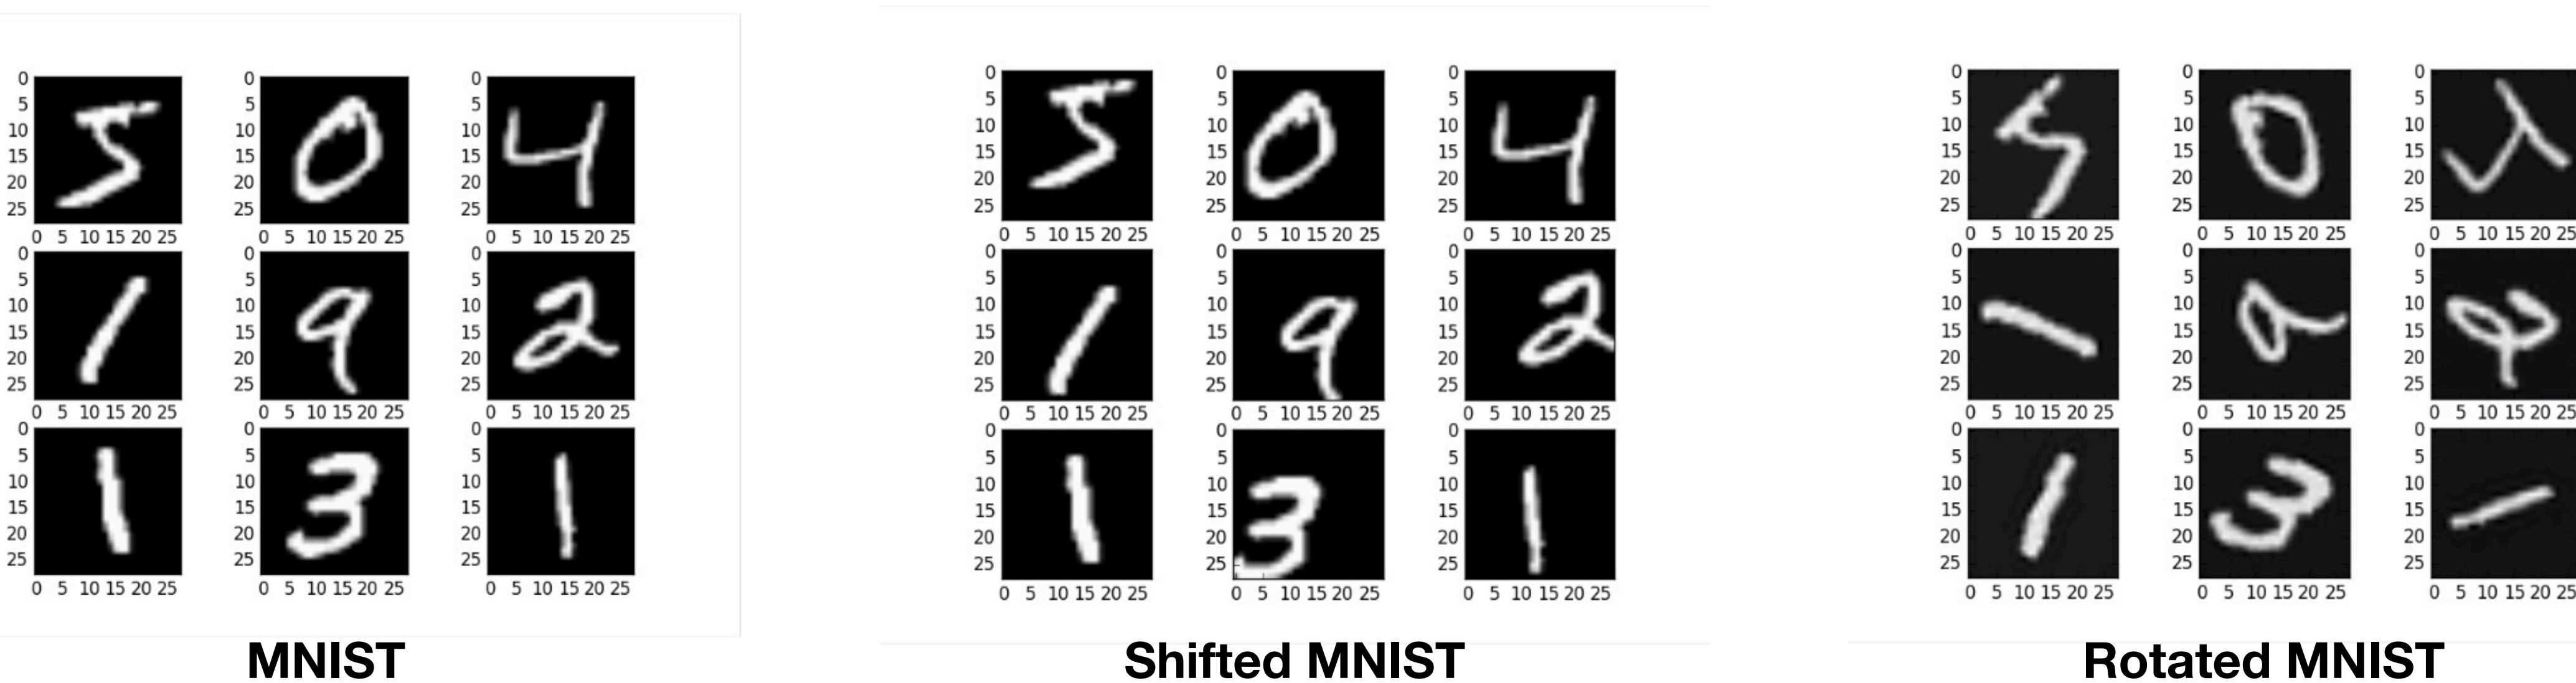

Popular architectures: VGG vs. ResNet

Source: the ResNet paper (CVPR 2016)

Data Augmentation

Data augmentation: generate new data from the data

Note dangers
of excessive
augmentation!

May eventually
confuse 6 and 9

Transformation $\tau : \mathbb{R}^d \rightarrow \mathbb{R}^d$ which preserves the labels (i.e., $y_x = y_{\tau(x)}$)

$$S = S_{train} \cup \{(\tau(x_i), y_i)\}_{i=1}^n$$

- We train on more data
- Encourages models to be invariant to τ
- It can be seen as regularization
- These transformations are task and dataset specific

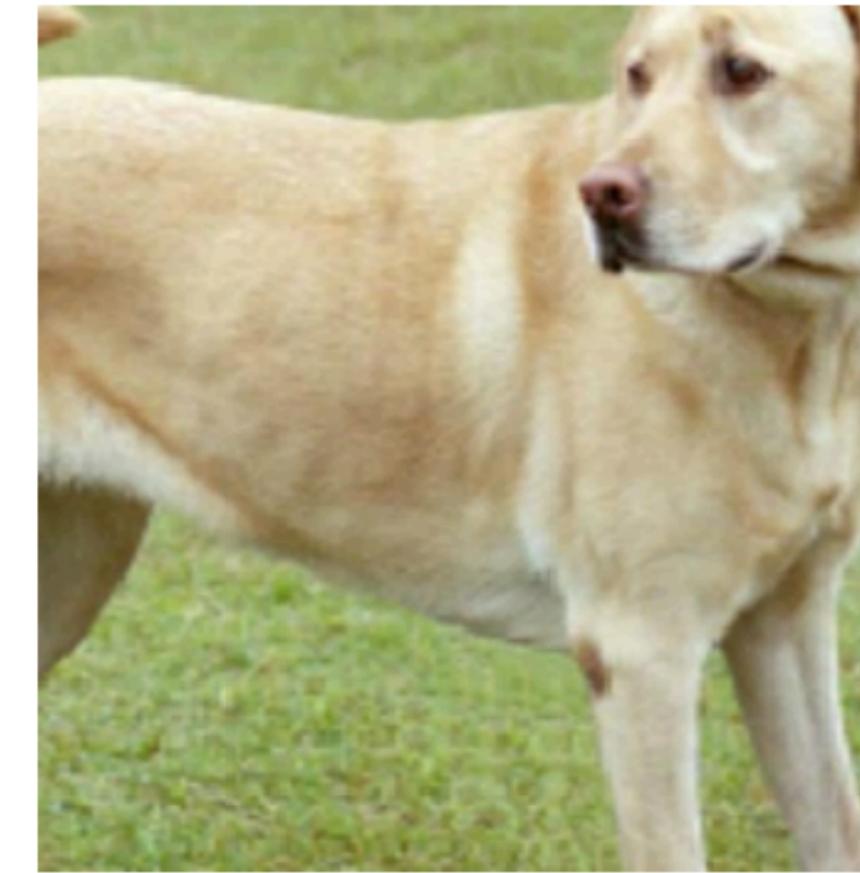

Data augmentation: pictures can also be cropped, resized, or perturbed by a small amount of noise

(a) Original

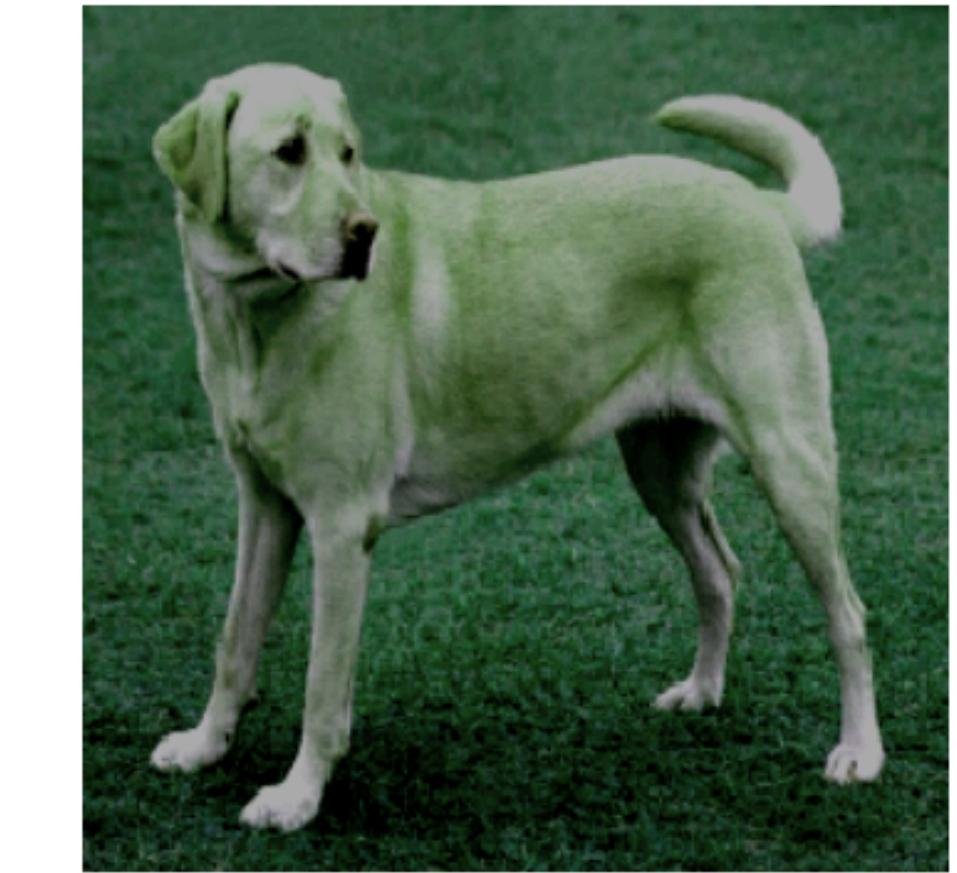

(b) Crop and resize

(c) Crop, resize (and flip)

(d) Color distort. (drop)

(e) Color distort. (jitter)

(f) Rotate $\{90^\circ, 180^\circ, 270^\circ\}$

(g) Cutout

(h) Gaussian noise

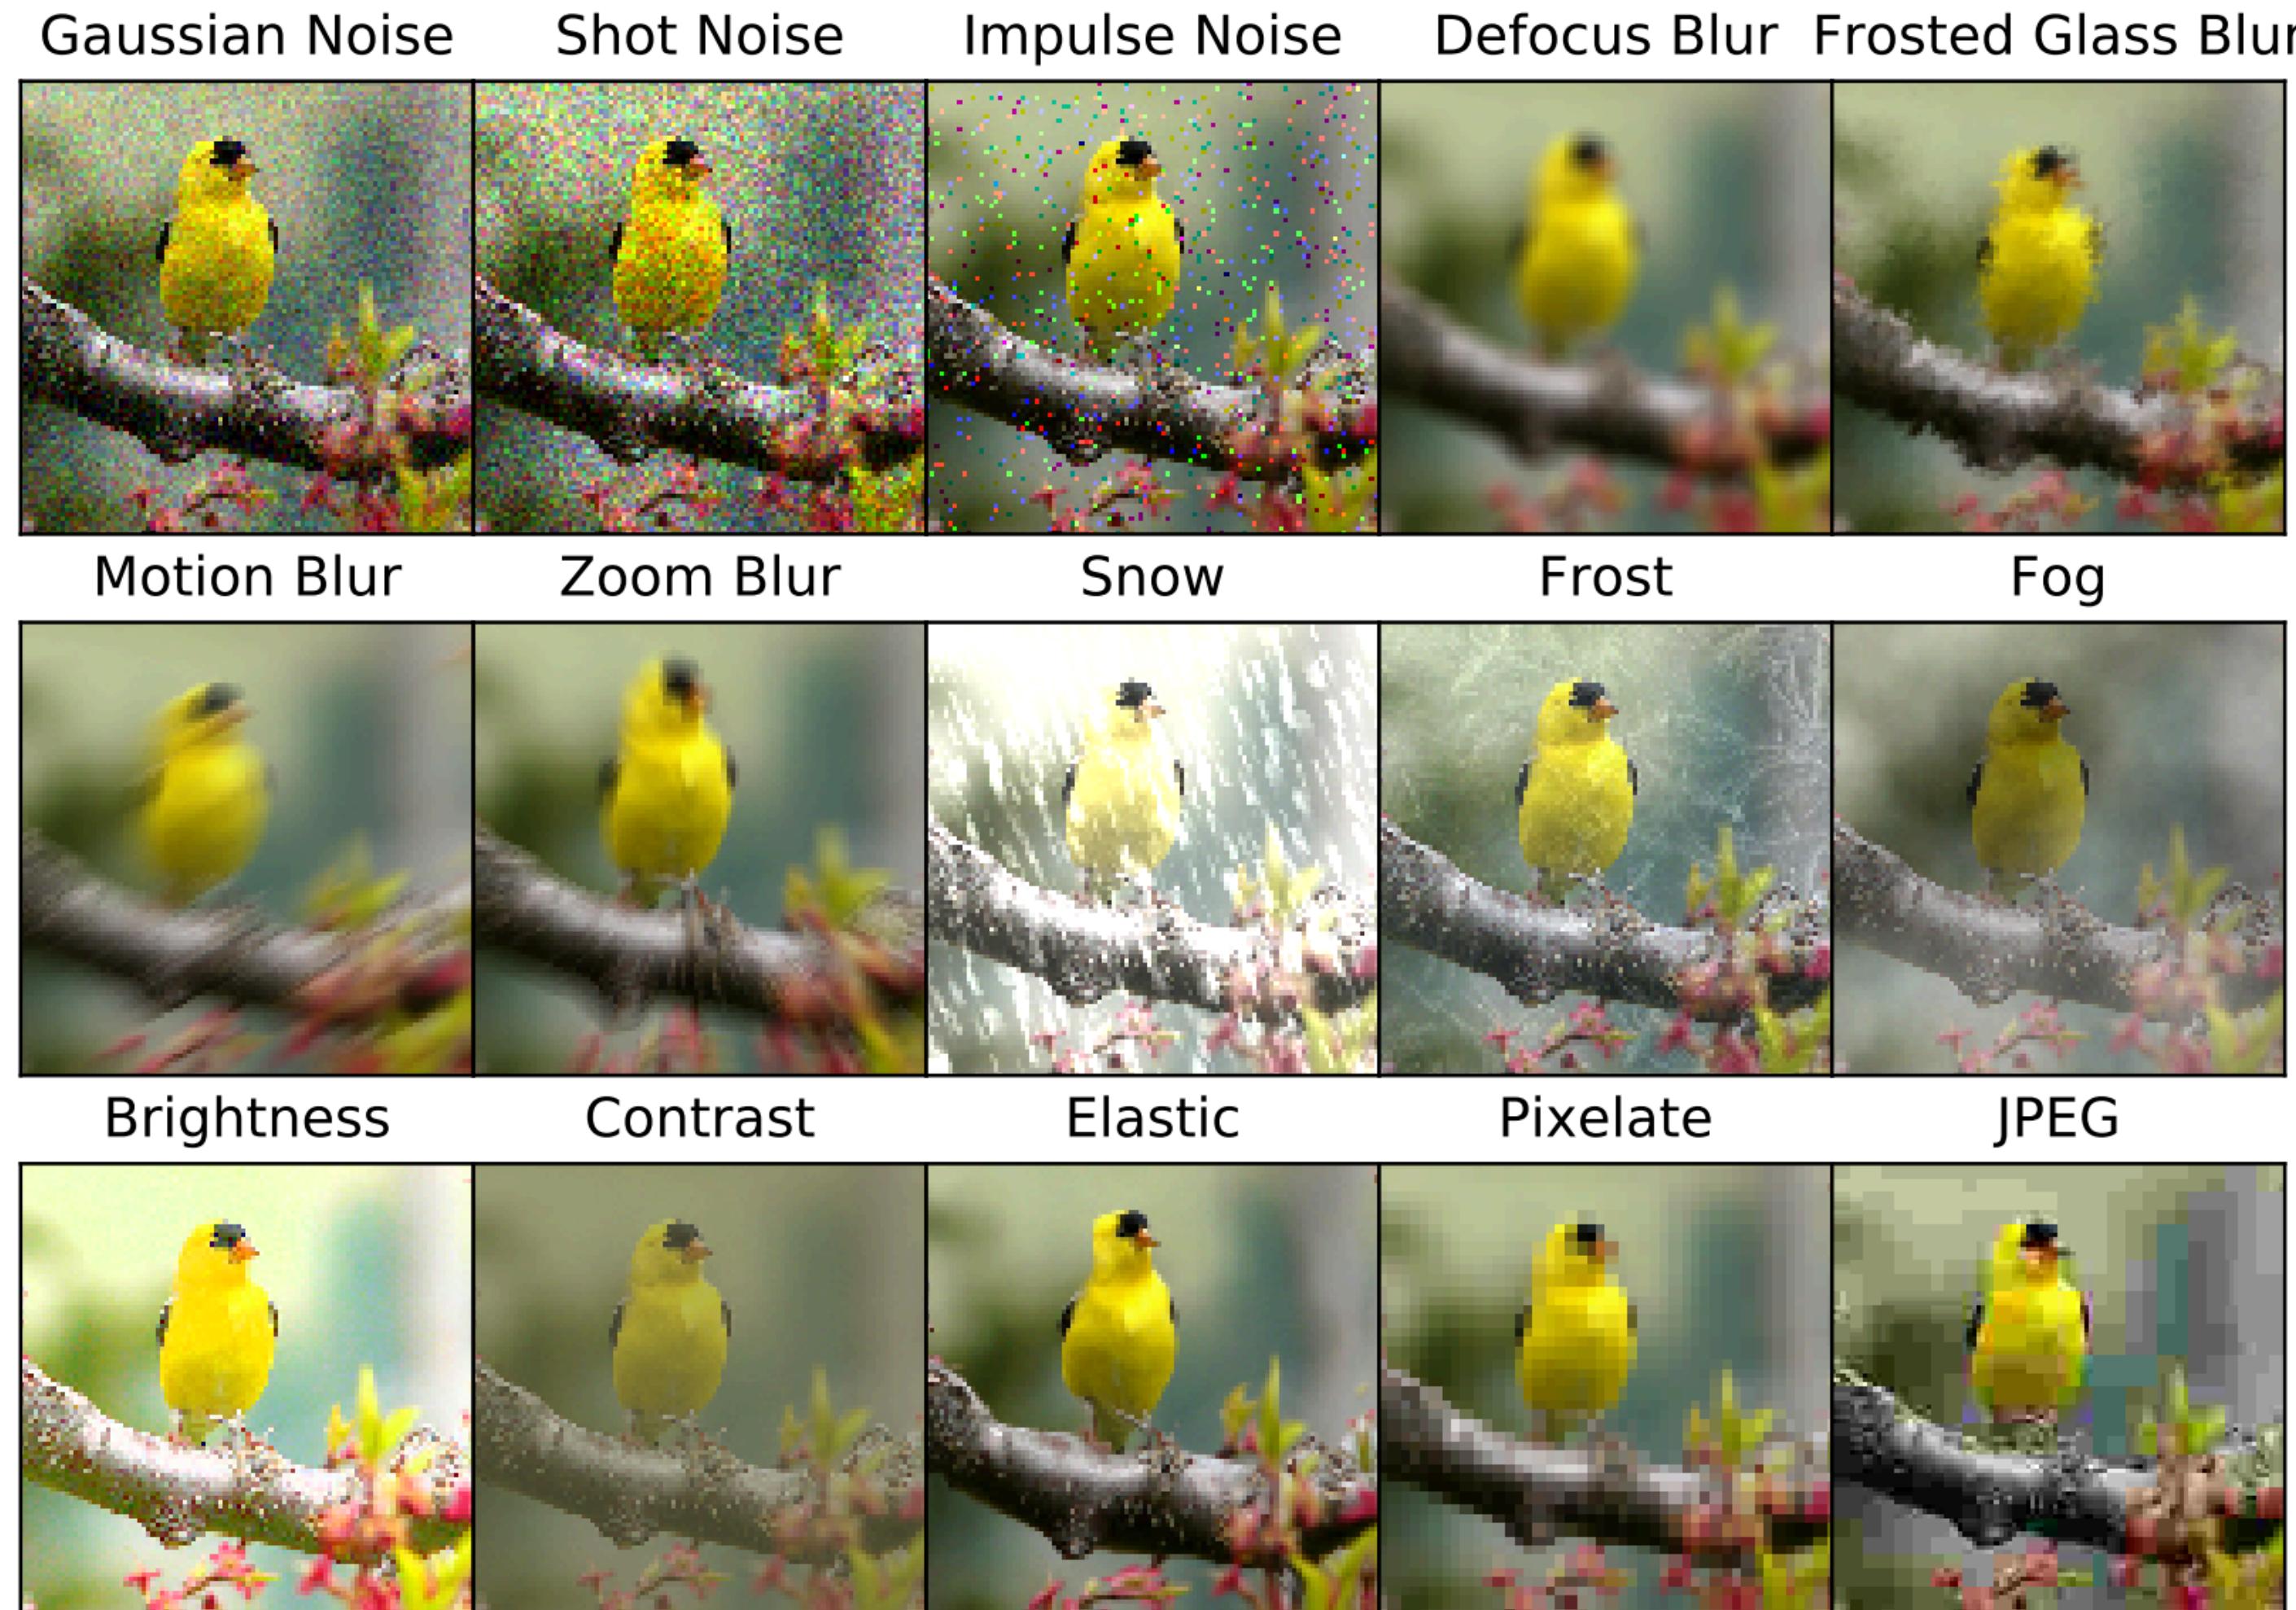

(i) Gaussian blur

(j) Sobel filtering

Data augmentation: generated corruptions

Weight Decay

Weight decay: ℓ_2 -regularization for NNs

It is standard practice to regularize weights without regularizing bias terms:

$$\min \mathcal{L} + \frac{\lambda}{2} \sum_l \|\mathbf{W}^{(l)}\|_F^2$$

Weight decay [1] favors small weights which can aid in generalization and optimization

Optimization with gradient descent:

$$(\mathbf{w}_{i,j}^{(l)})_{t+1} = (\mathbf{w}_{i,j}^{(l)})_t - \eta \nabla \mathcal{L} - \eta \lambda (\mathbf{w}_{i,j}^{(l)})_t = \underbrace{(1 - \eta \lambda)}_{\text{weight decay}} (\mathbf{w}_{i,j}^{(l)})_t - \eta \nabla \mathcal{L}$$

Interaction with BatchNorm:

- $\text{BN}(\mathbf{WX}) = \text{BN}(\alpha \mathbf{WX})$ for $\alpha \in \mathbb{R}_{>0}$ (assuming $\varepsilon \approx 0$)
- \mathbf{W} is scale invariant, hence, there is **no direct regularization effect from WD**
- However, the training dynamics differ [2]

Dropout

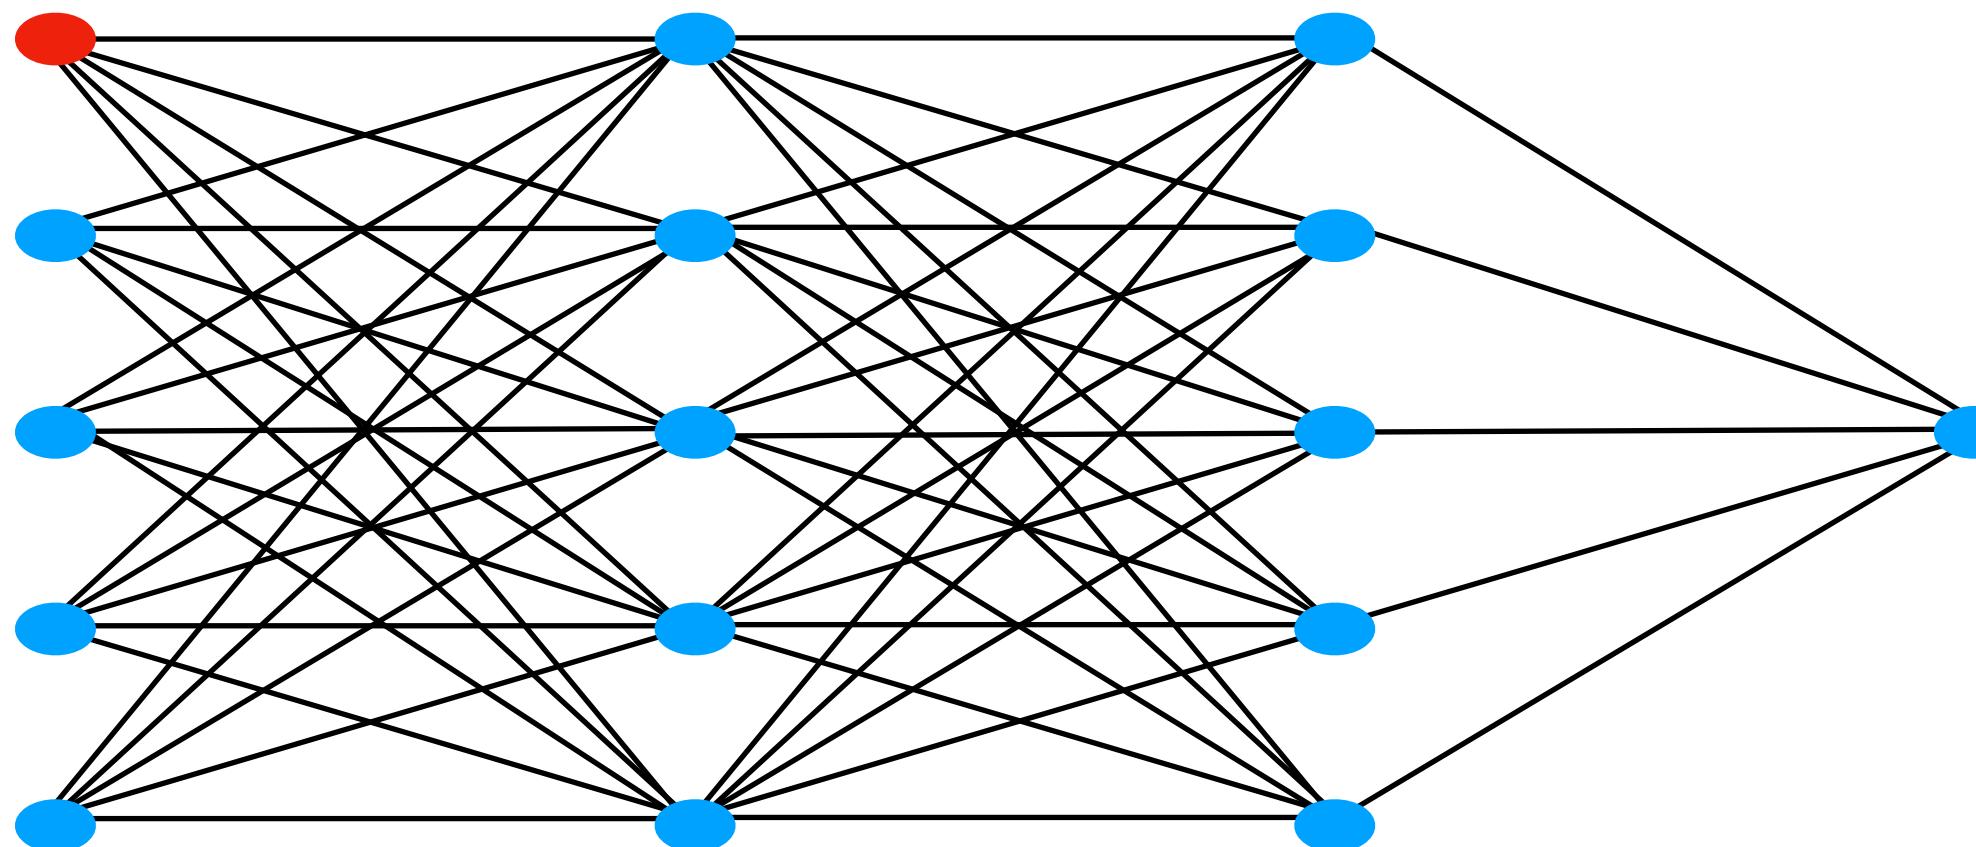

Dropout: randomly drop nodes

Def: At each training step, retain with probability $p^{(l)}$ each node in layer (l) :

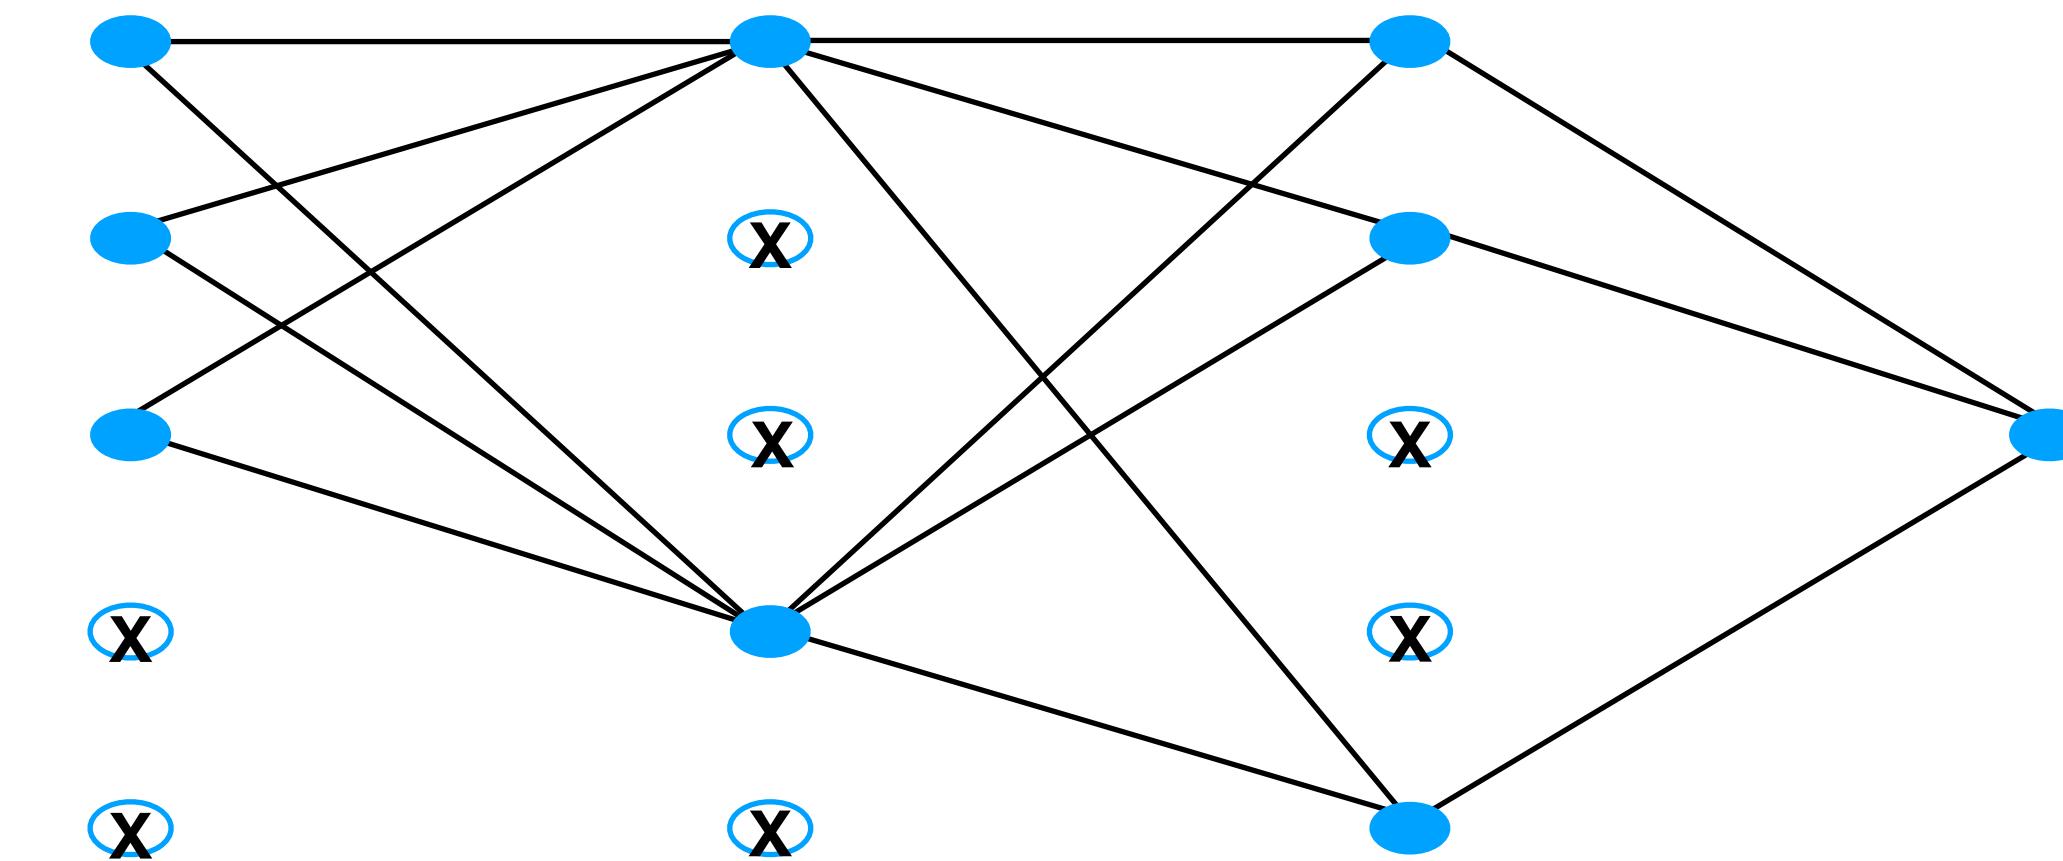

Dropout: training phase

Def: At each training step, retain with probability $p^{(l)}$ each node in layer (l) :

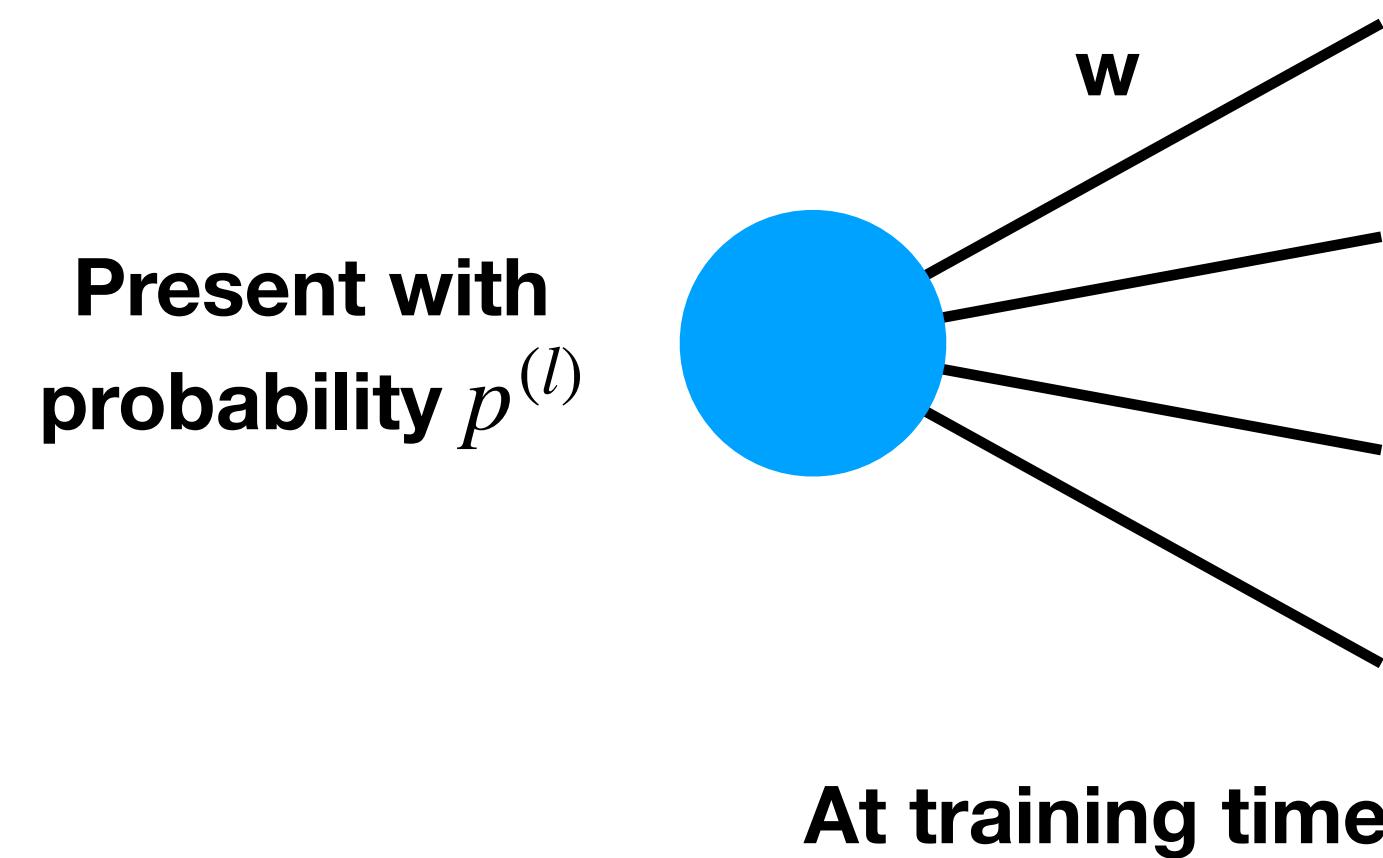

Original network

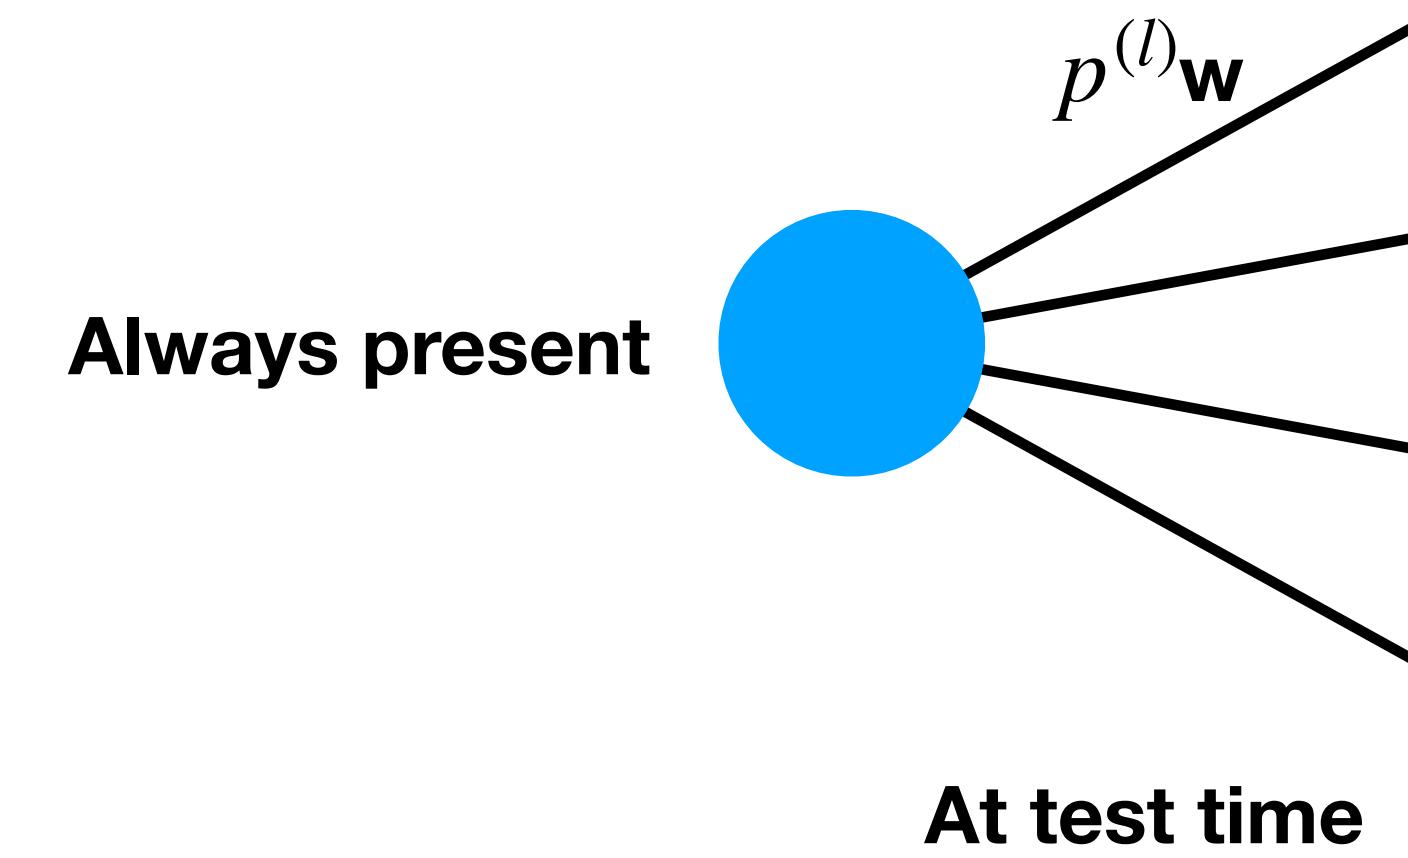

Random subnetwork

Run one step of SGD on the subnetwork and update the weights

Dropout: testing phase

At training time

At test time

Note: Variance is generally not preserved and as a result Dropout often works poorly with normalization

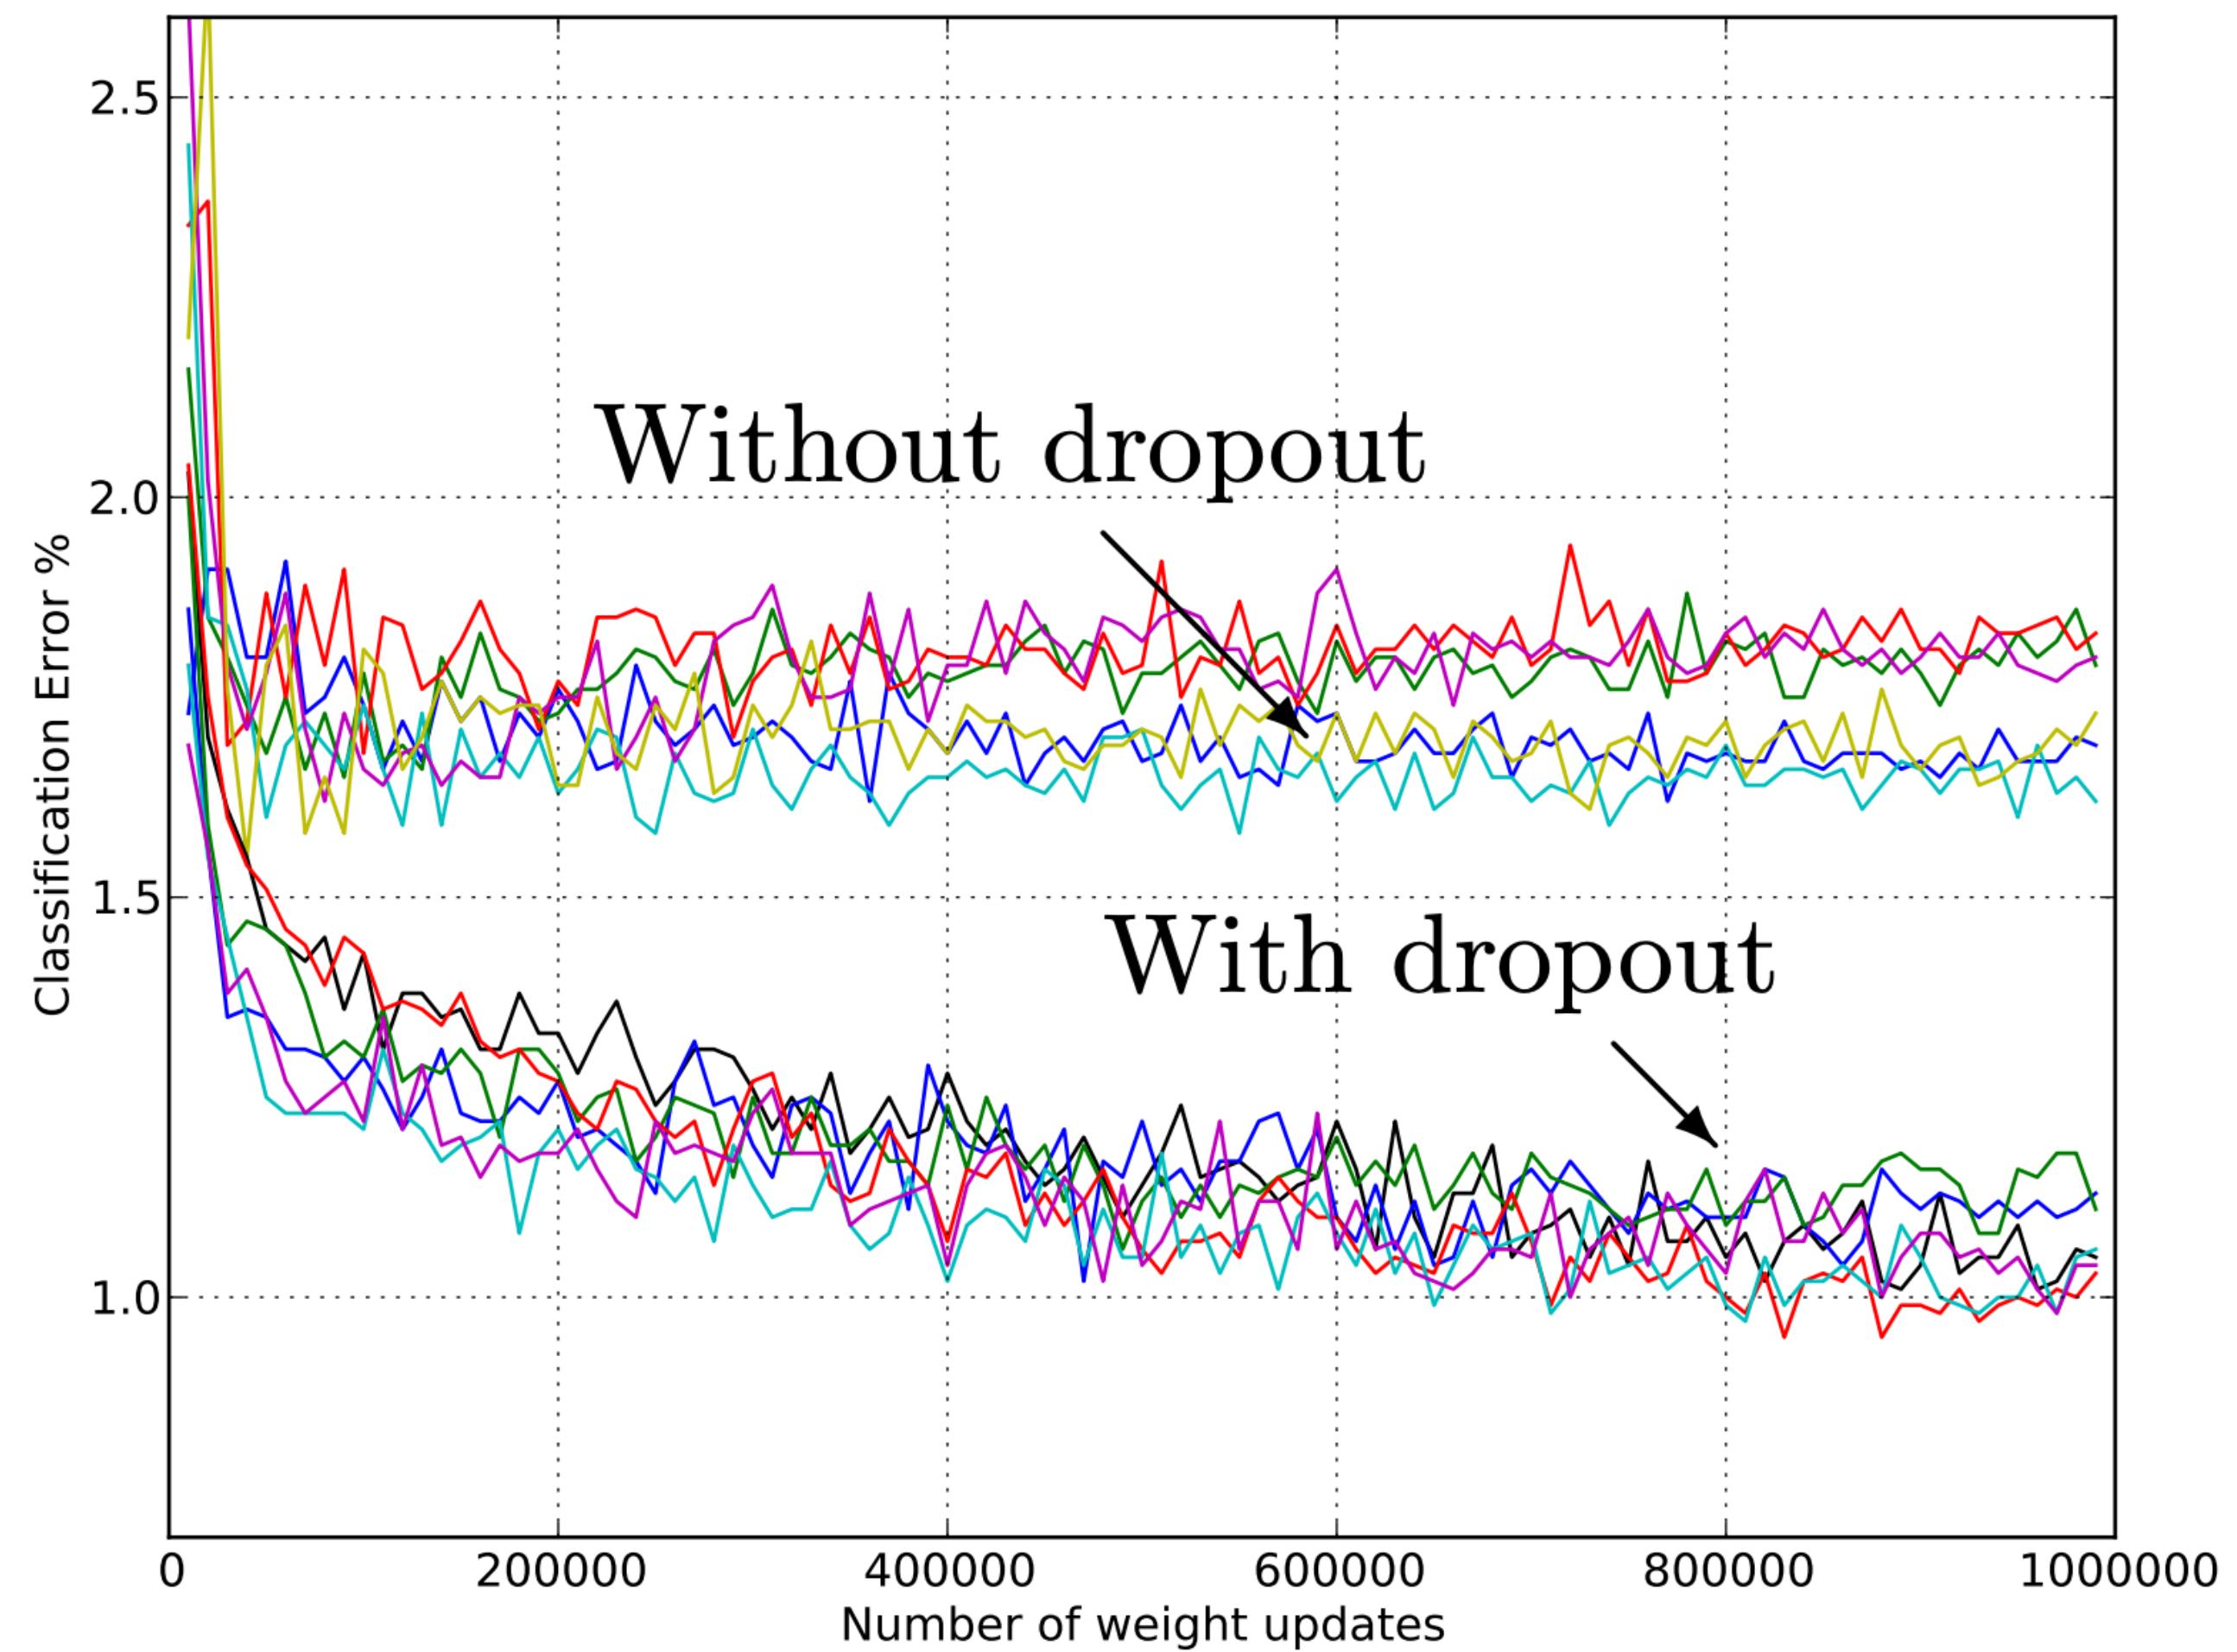

When testing:

- Use all nodes
- Scale each of them by the factor $p^{(l)}$ to ensure that the expected output (when considering the probability of dropping nodes during training) matches the actual output at test time

Remark: Weight rescaling can be implemented during training time by scaling the weights by $1/p^{(l)}$ after each weight update - this is how it is implemented in practice

Dropout: results

- **Setting:** Fully-connected networks of different width and depth on MNIST
- Dropout results in **lower test error**
- However, dropout typically requires more iterations to converge due to increased stochastic noise

() : best test accuracy during training, i.e., with early stopping

Recap

- Convolutional networks are composed of **sparsely connected convolutional layers** instead of fully-connected linear layers
- The same convolution is applied as a sliding window across all spatial locations
- **Data augmentation** usually results in a significant improvement in the model's generalization performance
- **Weight decay** and **dropout** can further enhance the performance, though typically to a lesser extent
